SOURCE: Ref. zh. Mekhan. Abs. 3B677

AUTHOR: Abuzova, F. F.; Chernikin, V. I.

TITLE: Losses from evaporation from underground reservoirs with a cross-section constant in height

CITED SOURCE: Tr. N.-i. in-t po transp. i khraneniyu nefti i nefteproduktov, vy*p. 2, 1963, 162-185

TOPIC TAGS: hydromechanics, diffusion, gas storage, petroleum storage, Stefanovskiy flow, atmospheric storage tank

TRANSLATION: The influence of Stefanovskiy flow on the distribution of concentration of vapors of a product in the gas space of an underground atmospheric reservoir is given. A comparison of the results obtained with experiments shows that errors connected with omission of Stefanovskiy flow can amount to 100%. The curves of determining the concentrations without counting Stefanovskiy flow give a lowered concentration at any point of the gas space. Curves including calculations of Stefanovskiy flow coincide satisfactorily with experimental data.

PHASE I BOOK EXPLOITATION 982

Voprosy geologii urana (Problems in the Geology of Uranium) 159 p. (Series: Atomnaya energiya. Prilozheniye, 1957, no. 6) 7,000 copies printed.

Resp. Ed.: Konstantinov, M.M.; Tech. Ed.: Usachev, G.L.

PURPOSE: This book is of interest to uranium exploration specialists and geologists studying associated minerals.

COVERAGE: The present collection of 12 articles by different authors discusses the genesis of uranium deposits, uranium mineralogy, and methods of research and analysis used in evaluating ores. Several new minerals are described and a review of aerogeophysical exploitation in the United States, Canada and Australia is given. The articles are accompanied by diagrams, tables, photographs, and bibliographic references.

AUTHOR CHERNIKOV, A.A., KRUTETSKAYA, O.V., ORGANOVA, N.I. 89-8-8/26

TITLE Sodium Autenite.
(Natroautenit)-Russian)

PERIODICAL Atomnaya Energiya, 1957, Vol 3, Nr 8, pp 135 - 140 (U.S.S.R.)

ABSTRACT In 1953 a new mineral was found in a Russian mountain massif- a hydrous sodium -uranium phosphate. The mineral belongs to the group of uranium micas, and is closely related to autonite with respect to its properties. The following experimental data concerning the new mineral are available:

a) Chemical composition:

UO_3	61,9 ÷ 62,53%	Co_2	0,24 %
P_2O_5	15,56 ÷ 14,69%	MgO	0,43 %
Na_2O	5,62 ÷ 6,88%	Al_2O_3	0,32 %
CaO	1,2 ÷ 0,14%	Fe_2O_3	0,97 %
SiO_2	1,6	H_2O	13,07 ÷ 14,84 %

b) Stoichiometric formula: $Na_2(UO_2)_2(PO_4)_2 8H_2O$

c) Specific weight: 3,584 g/cm^3

d) Crystal lattice spacing: a = 6,97 Å, c = 8,69 Å, c/a = 1,245

(3 tables, 2 illustrations and 6 Slavic references).

Exogenous epigenetic deposits of uranium; formation conditions (Ekzonennyye epigeneticheskiye mestorozhdeniya urana; usloviya obrazovaniya). Moscow, Atomizdat, 1965. 321 p. illus., biblio. Errata slip inserted. 1100 copies printed.

TOPIC TAGS: deposit formation, epigenetic theory, exodiagenetic deposit, surface uranium accumulation, uranium bituminous deposit, uranium deposit, uranium, nuclear fuel.

PURPOSE AND COVERAGE: This book is intended for readers specializing in the geology of ore deposits, in particular for those concerned with atomic raw materials, and also for students of higher-education institutions. In the book, for the first time in Soviet and foreign literatures, the epigenetic theory of uranium-deposit formation is expounded. Many Soviet and foreign source materials

AUTHORS: Borovikov, A.M., Kostarev, V.V., Mazin, I.P. and Chernikov, A.A.

TITLE: Relation between the magnitude of the radar signal reflected from a cloud and the cloud parameters

SOURCE: Tsentral'naya aerologicheskaya observatoriya. Trudy. no. 36. Moscow, 1961. Voprosy fiziki radiolokatsii oblakov, 14 - 30

TEXT: Atlas (Journ. of Met. v.11, no.4, 1954) and Donaldson (Journ. of Met., v.12, no. 3, 1955) have discussed the possibility of the measurement of the liquid-water content of clouds by radar methods and have concluded that this was possible. In view of the considerable scientific and practical importance of the problem, the authors undertook a theoretical and experimental study of this subject and the results are now reported. Theoretical analysis showed that the strength of the reflected radar signal provided information about the quantity

$$Z = \int_0^\infty n(r)\, r^6\, dr \qquad (4) .$$

Card 1/3

APPROVED FOR RELEASE: 06/12/2000 CIA-RDP86-00513R000308510018-5"

"APPROVED FOR RELEASE: 06/12/2000 CIA-RDP86-00513R000308510018-5

Since the liquid-water content is given by

$$w = \frac{4}{3} \pi \int_0^\infty n(r)\, r^3\, dr \qquad (5),$$

it follows that the relation between Z and w depends on the form of the particle-size distribution. Detailed examination of known drop-size distributions shows that w can be determined provided there are not too many large particles. The experimental part was carried out from the aerological radar station developed and built at TsAO and operating at $\lambda = 3.2$ cm. The aim was to obtain radar data which could be compared directly with aeroplane observations. A description of the apparatus is said to be available elsewhere [Abstracter's note: reference not given]. A detailed numerical table is reproduced showing a comparison between radar observations and observations carried out from an aeroplane with the aid of the drop-size meter developed by Nevzorov at TsAO (c.f.* pp. 3-13 of this issue). General conclusions: strong signals ($Z > 10^{-15}$ cm^3) are due to large particles

APPROVED FOR RELEASE: 06/12/2000 CIA-RDP86-00513R000308510018-5"

"APPROVED FOR RELEASE: 06/12/2000 CIA-RDP86-00513R000308510018-5

so that practically all the characteristics obtained with the radar equipment refer only to the large-particle "cloud". Since the presence of even a small number of such particles in clouds has an appreciable effect on the reflected signal, and since the strength of the signal is very sensitive to the size spectrum, it is considered that the relation between Z and w cannot, in practice, be separated from the general background due to other factors, i.e. w cannot be determined from Z alone. Thus, the "optimistic conclusions" of Atlas and Donaldson are considered unfounded. It is noted, however, that this does not mean that radar methods cannot be used in cloud studies. On the contrary, because the radar signal provides information about the presence and behaviour of large particles in clouds, this opens up new possibilities in the experimental study of clouds and precipitation.
There are 2 figures and 4 tables.

TITLE: Radar Measurement of Turbulence in Clouds (Radiolokatsionnoye izmereniye turbulentnykh dvizheniy v oblakakh)

PERIODICAL: Meteorologiya i Gidrologiya, 1958, Nr 5, pp 12-19 (USSR)

ABSTRACT: In recent years the possibility of a further perfection of the method and an extension of program of the meteorological observations by means of these methods of operation already introduced arose. This development is possible in 3 directions complementing each other:
1) Modernization of the usual apparatus according to the objects and the requirements of the meteorologists.
2) Elaboration of a special aerological apparatus.
3) Determination of data on reflection-sources of signals of a meteorological origin. The above-mentioned methods in a certain sense are inertia-like. The increase in this property can considerably increase the domain of employment of these methods in aerology. At the same time it is beyond that the inertia-less method, i. e., the observations of every impulse separately, can give valuable

additional information on the physical properties of meteorological phenomena. Observations according to the last method are described. The measurement mentioned in the title is explained by figure 1. At the output of the receiver a sequence of impulses of the radio-echo (Figure 1 v) forms. For the determination of the connections between the fluctuation amplitudes of the sequence of reflected signals and the mean square velocity of the chaotic motions of dispersing particles the authors employ a theory which was worked out during the investigation of the statistical nature of the ionosphere (References 1,2). A measuring method of the velocity of the radio signal expressed in formulae (1) - (15) is considered inconvenient by the authors. The estimation of the velocity with regard to orientation is expressed by the formula:

$$v_s = \frac{n\lambda}{2\Delta T} \quad (17)$$

The counting of the distinctly marked maxima during the time of observation and the multiplication with a con-

APPROVED FOR RELEASE: 06/12/2000 CIA-RDP86-00513R000308510018-5"

"APPROVED FOR RELEASE: 06/12/2000 CIA-RDP86-00513R000308510018-5

stant coefficient $\frac{\lambda}{2\Delta T}$ is sufficient. A block scheme of the measuring device is shown by figure 2. Figure 3 gives recordings of the pulse-sequence. The pulses followed each other at 1/1500 seconds distance. The demands made on the apparatus mainly require that the frequency of the magnetron during the observation may change by a amount which is much smaller than $\frac{1}{0}$, that means:

$\Delta f \ll \frac{1}{\tau}$. By the investigation of the fluctuation of the signal which is reflected by 2 weakly fluctuating local objects the frequency drop can be estimated. By the above-mentioned method the chaotic motions of the diffusers in different types of clouds and precipitation were investigated in summer and fall 1957. The distribution of the amplitudes of the received signal well agrees with the theoretical data. The not yet numerous results obtained from the work permit some conclusions on the amount

of chaotic agitations in the clouds. The values of v_o for a vertical column of 150 m brought to an average, lie between 0,1 and 2,0 seconds. The highest values were obtained for thunder-clouds, the lowest ones for the stratus clouds. The method proved to be usable for this purpose.

TITLE: On the effect of fluctuations in echo signals from clouds on the operation of a store

SOURCE: Tsentral'naya aerologicheskaya observatoriya. Trudy. no.36. Moscow, 1961. Voprosy fiziki radiolokatsii oblakov, 118-125

TEXT: In order to extend the range of applications of an aerological radar apparatus in cloud observations, a storage circuit was incorporated in the receiving part of the equipment. This ensured that weak echoes would be detected and their intensity measured. The method requires a knowledge of both the amplitude characteristics of the store and of the dependence of the "efficiency" (i.e. the improvement in the signal to noise ratio) on the width of the fluctuation spectrum of the radio echoes. A statistical analysis is now given of the amplitude characteristics of a store of this type for a constant and a fluctuating signal. Analytical expressions are derived for the amplitude at the output of the integrator as a function of the signal-to-noise power level ratio. Comparison with experimental

"APPROVED FOR RELEASE: 06/12/2000 CIA-RDP86-00513R000308510018-5

data showed that the theoretical expressions are in good agreement with experimental data. The "efficiency" is also discussed theoretically and the analysis is applied to a store developed at the Laboratoriya radiolokatsii TsAO (Radar Laboratory of TsAO) (Otchet laboratorii radiolokatsii TsAO (Report of the Radar Laboratory of TsAO) 1959). Comparison of direct measurements with the theoretical calculations showed that the "efficiency" for a fluctuating signal is the same, to within experimental error, as the efficiency for a constant signal. The general conclusion is that both theory and experiments indicate that the effect of fluctuations in the echo signals on the parameters of the above store is negligible. There are 5 figures.

TITLE: A method of determining wind velocity by radar

PERIODICAL: Byulleten' izobreteniy, no. 7, 1962, 48

TEXT: Class 42i, 20_{01}. No. 146078 (699558/26-9 of February 28, 1961). 1) A method of determining wind velocity by observing objects moving in the wind stream through radar is distinguished by the fact that hydrometeors or artificial dispersion formations are used as observation objects. 2) A method as in 1, but distinguished by the fact that the wind velocity is determined by simultaneous reception of two signals. One is reflected from a "local object" and the other from a hydrometeor located at a distance equal to the distance of the "local object". 3) A method as in 1 and 2, but distinguished by the fact that the wind velocity is determined from the shift of the second maximum of a spectrum envelope observed on the indicator of a spectrum analyzer in respect to the first basic maximum located on the axis of the frequencies.

TITLE: Method of atmospheric wind-sounding. Class 42, No. 157565

SOURCE: Byul. izobret. i tovarn. znakov, no. 18, 1963, 79-80

TOPIC TAGS: wind sounding, atmospheric wind sounding, atmospheric turbulence

ABSTRACT: The patent introduces a method for sounding wind in the atmosphere based on the use of the Doppler effect and an accompanying passive coherent-pulse radar-station reflector to determine the projection of wind velocity on a radar beam. The signal from the phase detector is conveyed to a frequency detector to determine simultaneously the mean velocity and parameters of atmospheric turbulence. The frequency detector converts the Doppler frequency into voltage which determines the amount and scale of turbulence, the integrator, which determines the projection of the mean wind velocity, and the recorder, which corrects wind and atmospheric data according to the antenna angle. ABSTRACT: The use of ordinary radar apparatus in aerology for observation of many meteorological objects is impossible because of inadequate sensitivity. The signal reflected from the object often is so weak that it is lost in the instrument noise. The authors therefore have devised a signal accumulator which improves the signal-to-noise ratio at the output of the receiver of an ordinary centimeter-range radar set. The signal accumulator makes it possible to detect a weak radar echo, determine the coordinates of its source and obtain data on the strength of the reflected signal. A simplified block diagram of the detection of a weak signal by use of this device is shown in Fig. 1 of the Enclosure. The amplitude characteristics and gain of the signal accumulator are described. A very detailed

observed phenomenon. It is shown that the sources of reflection from a "clear" sky are regions of inhomogeneities of the refractive index, which produce highly directional reradiation in the centimeter band. An estimate of the minimum dimensions of these zones is given, and coefficients of reflection from the investigated inhomogeneities are also determined. It is established that in the summer months the concentrations of the inhomogeneities amount to 10^3--10^4 km^{-3}, and in those cases when the echo forms layers it reaches 10^5--10^6 km^{-3} and more. Under these conditions, as shown by preliminary estimates, the observed reflection sources make an appreciable contribution to the scattered field during the propagation of the waves beyond the horizon, and in some cases they can apparently completely govern this phenomenon. Bibliography, 35 titles.

ABSTRACT: A description of the statistical meteorological radar method is given. The full theory of the method is described and it is shown that the radar method can be used to measure wind velocity and the microcharacteristics of precipitation. Formulas are given for use with the radar signal spectrum for determining the mean rate of energy distribution (ε) in a turbulent flux, the wind velocity gradient, drop-size distribution, and other parameters. Instruments and observation methods are described. Results are given for observations in clouds of different genera for which the values ε have been computed. The results of wind observations are described and it is shown that
