Title : Variations in the Natural Losses in Meat During Freezing

Orig Pub : Myasnaya industriya SSSR, 1955, No 6, 11-15

Abstract : The freezing of meats has been investigated and a method is proposed for determining the dehydration of the meat during freezing. On the basis of an analysis of the heat balance during freezing and the theory of controlled cooling rates, the authors conclude that the rate of dehydration of the meat during freezing follows an exponential law:

$$V = V_n e^{-m \tau^2}$$

Card : 1/4

USSR / Chemical Technology. Chemical Products and Their Application. Food Industry.

I-30

Abs Jour : Ref Zhur - Khimiya, No 3, 1957, No 10412

Abstract : where U is the rate of dehydration at any given instant during freezing in gms/hr,  $\tau$  is the freezing time in hours,  $U_0$  is the initial rate of dehydration for  $\tau = 0$ , and mg is a constant characteristic of a given freezing temperature and of the dehydration process. The dehydration at any given moment during freezing may be calculated from the expression:

$$J = U_0 / mg [1 - e^{-mg\tau}]$$

Experiments have been conducted on the separate cooling of a hind quarter weighing 34.65 kg and of a gluteus muscle weighing 1.297 kg at an air temperature of 2°, a relative humidity of 95%, and rate of travel of 0.1 m/sec. It has been found that for the quarter  $mg = 0.1266$  and for the

Card : 2/4

USSR / Chemical Technology. Chemical Products and Their Application. Food Industry. I-30

Abs Jour : Ref Zhur - Khimiya, No 3, 1957, No 10412

Abstract : gluteus muscle mg = 1.2254. Good agreement was observed between the experimentally observed values and calculated values. Check tests on commercial butts showed that the difference between the calculated and measured values was of the order of 2-3%. The authors recommend that three weighings be made when the natural losses in meat cooled under different technical conditions with a central-layer temperature of 30-15° are to be determined. From the two changes in the degree of dehydration,  $g_1$  and  $g_2$  at times  $\tau_1$  and  $\tau_2$ , where  $\tau_2 = 2\tau_1$ , a system of equations may be set up and the values of mg and  $U_{\text{m}}$  can be calculated; substitution of these values into the basic equation gives the dehydration for any cooling time  $\tau$ . A relationship has been established between the value of mg and the

Card : 3/4

USSR / Chemical Technology. Chemical Products and Their Application. Food Industry. I-30

Abs Jour : Ref Zhur - Khimiya, No 3, 1957, No 10412

Abstract : cooling rate m (RZhKhim, 1956, 41791):

$$\text{m}_{\text{ng}} = 1.36 \cdot m + 0.0067.$$

The value of  $U_n$  is not constant for different meats and depends on the temperature drop, the shape and physical characteristics of the meat. The effect of the flow rate of air during cooling on the weight loss in the meat has been investigated, as has the dependence of the dehydration during cooling on the storage period, periods of 2-3 days being used.

AUTHORS: Jakowlew, J. W., Alina, Z.

TITLE: The determination of trace quantities of manganese and zinc in metallic bismuth by the method of radioactivation

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 22, 1962, 130, abstract 22D106 (Pierwsze krajowe sympoz. zastosowań izotopów techn., Rogów, June 8-12, 1960, Warszawa, no. 10, 1961, [Pol.] summaries in Russ. and Eng.])

TEXT: To determine Mn and Zn in high-purity bismuth, a specimen ( $\sim 1$  g) in a quartz crucible is irradiated by a neutron beam of slow neutrons ( $8 \cdot 10^{12}$  neutrons/cm<sup>2</sup>/sec) for 20-48 hrs. 10-20 mg each of Mn and Zn are added to the irradiated specimen as carriers (in the form of chloride solutions), and it is dissolved in aqua regia. The solution is concentrated with HCl. The residue is diluted with water to reduce the concentration of HCl to 0.6-0.8 N, and H<sub>2</sub>S is bubbled through it to precipitate Bi, Cu, As and Sb as sulfides. After separation, the filtrate

The determination of trace ...

(containing Mn and Zn) is boiled with  $\text{HNO}_3$ , then neutralized by an  $\text{NaOH}$  solution to a weakly acid reaction, and  $\text{NH}_4\text{OH}$  and  $\text{H}_2\text{O}_2$  are added to precipitate Mn as  $\text{MnO}_2$ . After separation, the precipitate is dissolved in a mixture of  $\text{HNO}_3$  with  $\text{H}_2\text{O}_2$  while being heated, and as the  $\text{H}_2\text{O}_2$  decomposes,  $\text{MnO}_2$  is precipitated by adding solid  $\text{KClO}_3$  (to separate Mn from the rare-earth elements). The precipitate is again dissolved, solutions of Bi, Cu, Zn and Ni salts are added as reverse carriers, and precipitation is repeated by adding  $\text{MnO}_2$ . The  $\text{MnO}_2$  is reprecipitated once again. The precipitate is dissolved.  $\text{NH}_4\text{Cl}$  and  $\text{Na}_2\text{HPO}_4$  and  $\text{NH}_4\text{OH}$  solutions are added. The evolved  $\text{MnNH}_4\text{PO}_4$  is separated, dried, and the intensity of  $\beta$ -radiation caused by the presence of  $\text{Mn}^{56}$  is measured by a Geiger counter. The precipitate is calcined, weighed and the weight used to calculate the percentage of Mn evolved from the specimen. The Mn content is found by comparing the registered activity with that of a precipitate evolved by the same method from a specimen of bismuth to which a known quantity of Mn was

The determination of trace ...

added before irradiation. ZnS is precipitated in an acetate medium from a filtrate (obtained after the separation of MnO<sub>2</sub>) containing Zn. The precipitate is dissolved in 10 ml of 1 n HNO<sub>3</sub>, heated to boiling point, a solution of (NH<sub>4</sub>)<sub>2</sub>Hg(SCN)<sub>4</sub> is added, the precipitated ZnHg(SCN)<sub>4</sub> is removed and dissolved in HNO<sub>3</sub> with application of heat. The solution is diluted to 10 ml and HgS precipitated by bubbling H<sub>2</sub>S through it. The filtrate is diluted to 30 ml, a solution of Bi salt is added (as a carrier) and H<sub>2</sub>S bubbled through. The precipitate is separated, the filtrate is heated to boiling point, a solution of FeCl<sub>3</sub> (carrier) is introduced, and Fe(OH)<sub>3</sub> is precipitated by adding NH<sub>4</sub>OH. HNO<sub>3</sub> is added to the filtrate (up to 1 mol/l) and Zn is precipitated as ZnHg(SCN)<sub>4</sub>. The precipitate is separated, flushed with water, alcohol and ether, and after drying, the activity caused by the presence of Zn<sup>69</sup> is measured. The method was used to determine 10<sup>-4</sup> to 10<sup>-6</sup>% of Zn and 10<sup>-7</sup> to 10<sup>-8</sup>% of Mn in metallic

TITLE: Investigation of the plasma injected into a magnetic trap with the aid of a conical theta-pinch

SOURCE: Zhurnal tehnicheskoy fiziki, v. 36, no. 5, 1966, 877-880

TOPIC TAGS: plasma gun, plasma source, plasma injection, magnetic pinch, plasma diagnostics, plasma shock wave, shock wave physics

ABSTRACT: The authors briefly describe the production and diagnosis of the plasma that was injected into a magnetic trap in the experiments of A.M. Iskol'dskiy, R.Kh. Kurtmullayev, Yu.Ye. Nesterikhin, and A.G. Ponomarenko (ZhETF, 47, No. 8, 1964). The plasmas (ion density about  $10^{13} \text{ cm}^{-3}$ ) were produced with the aid of a conical theta-pinch. Approximately  $0.1 \text{ cm}^3$  of D<sub>2</sub> or He was admitted to the vacuum chamber and a 2 μF 20-40 KV capacitor was discharged through the ionizing winding some 300-400 microsec later. The heated plasma entered the 150 cm long 10 cm diameter region between the two magnetic mirrors (mirror ratio ~ 1.4, magnetic field strength ≤ 3 kOe) through one of the mirrors, the field strength in which was less than that in the other by a factor of 1.3. Diagnosis of the plasma was effected with the aid of 0.4,

2

0.8, and 3 cm microwaves, an x-ray detector, an electrostatic analyzer, and a special ion collector similar to that described by M.V.Babykin et al. (ZhETF, 46, 511, 1964). The last was mounted in the region of one of the magnetic mirrors and was so designed that only ions with Larmor radii exceeding a preset value could reach the collecting electrode. A small number of high energy charged particles (energies up to 5 keV) were observed; these are ascribed to formation of a plasmoid in the conical plasma gun during the first half-period of the discharge. Most of the charged particles in the magnetic mirror machine had energies of the order of 100 eV; the density of particles with energies between 20 and 200 eV decreased exponentially with a time constant of 80-90 microsec. It is concluded that by means of external injection (fast theta-pinch) a plasma with a density of  $10^{13} \text{ cm}^{-3}$  and an average charged particle energy of 100 eV can be obtained in a magnetic mirror machine in which the magnetic field strength is between 1 and 3 kOe, and that such plasma can be employed to investigate the physics of collisionless shock waves. The authors thank R.Z.Sagdeev for his interest in the work and V.Pil'skiy for assistance with the measurements.

ABSTRACT: An Author Certificate, issued for a device which measures velocity, distance traversed, and time, combines a high-precision tellurometer, a phase recorder equipped with a unit for converting sinusoidal signals to pulsed signals, and a unit for measuring phase differences. Readings are made visually. The circuit connections of the device, consisting of a series of computer-type modules, are described in detail.
