TITLE: Investigation of the transient characteristics of the recovery of the inverse resistance in silicon pn junctions

SOURCE: AN AzerbSSR. Doklady, v. 21, no. 1, 1965, 14-18

TOPIC TAGS: silicon diode, pn junction, transient characteristic, inverse resistance, recovery time

ABSTRACT: The authors investigated the effect of reversal of the bias polarity on pn junctions obtained by diffusion of aluminum in n-Si with resistivity 10² ohm-cm. The pulses were applied to the investigated diode from a square-wave generator, and the inverse bias was applied from a rectifier. The ratio of the areas under oscillograms of the forward and backward current is shown to be a measure of the recovery of the inverse resistance of the diode. The experimental results are in satisfactory agreement with theoretical papers by

Card 1/2

L 59487-65

ACCESSION NR: AP5011793

others. The connection between these results and the lifetimes of the carriers in various parts of the diode and the pulse duration is discussed. It is shown that if ratio of the pulse duration to the base lifetime is small, the transient characteristics obtained make sense. In the case when this ratio is large, they make it possible to determine the lifetime of the minority carriers in the diode base.

TITLE: Reactive properties of reverse-biased silicon p-n junctions

SOURCE: Radiotekhnika i elektronika, v. 11, no. 7, 1966, 1336-1337

TOPIC TAGS: semiconductor device, pn junction

ABSTRACT: The reactive properties of low-volt (6 v breakdown) p-n junctions made from n-Si with a resistivity of 0.03--0.05 ohm·cm were investigated. Measurements were made at temperatures of -196--130C and at frequencies of 0.4--600 kc. Plots of junction capacitance vs. reverse bias at room temperature, for 5--100--200--400--600-kc, are shown. In the far-from-breakdown region, the

Card 1/2

UDC: 539.293.011.41

ACC NR: AP6023882

capacitance is independent of the small-signal frequency and decreases when the bias voltage increases, approximately as $C = U_{rg}^{-1/2}$. In the breakdown region, at lower frequencies, the capacitance rapidly increases with the bias voltage; at higher frequencies, the capacitance drops to zero and turns into inductance. A physical explanation is offered. Orig. art. has: 1 figure.

TITLE: The effect of high-temperature thermomechanical treatment on the structure and properties of austenitic steel

From: Moscow, Institut inzhenerov zheleznodorozhnogo transporta, Trudy, no. 195, 1969. Voprosy polysheniya dolgovechnosti detalей podvizhnogo sostava / Questions in increasing the durability of rolling stock and its maintenance, part 1, p. 69

TOPIC TAGS: automatic coupling, thermomechanical treatment, austenitic steel, austenitic steel, steel heat treatment, steel hardening, steel mechanical properties, letter pub

ABSTRACT: The author calls attention to the great importance of increasing the strength of railroad automatic coupling mechanisms, particularly of the draw spike mechanism of the car. In recent years, much attention has been given to thermomechanical treatment, which is a combination of plastic deformation with immediate tempering. In this connection, it is observed that if the plastic deformation of the austenite is effected at temperatures higher than that of recrystallization.

TOPIC TAGS: *CHROMIUM STEEL, SILICON STEEL*, steel, thermomechanical property / 37KhS steel, 38KhS steel

ABSTRACT: This is a presentation of the results obtained in an investigation of the influence of thermomechanical treatment under two regimes on the mechanical properties of steels 37KhS and 38KhS. The regimes are: 1) heating to 1150C, holding for 2 hours, stamping with 2-5 blows, oil quenching; 2) austenite formation at 900C for 30 min, 5-7 hammer blows, and oil quenching. The specimens were formed as wedges of a tension clevis for an automatic connector. After quenching, annealing is conducted at 200, 300, 400, 500, and 600C. A graph describing the influence of annealing temperature on the steel properties is included. Thermomechanical treatment of the described regime significantly improves the mechanical properties of Cr-Si steel. Bibliography of 4 titles. *(translation of an abstract)*

TITLE: Mechanism of the restoration of the adrenergic mediator reserves in axonal endings

SOURCE: Fiziologicheskiy zhurnal SSSR, v. 52, no. 1, 1966, 29-33

TOPIC TAGS: dog, nerve fiber, muscle physiology, hormone, gland, drug effect, neurology, animal physiology, nervous system drug

ABSTRACT: Investigations were conducted to determine the possibility of the restoration of excitation transmission by the sympathetic nerve smooth muscle halted as a result of the exhaustion of mediator reserves in the axonal endings by the administration of reserpine and the extirpation of the substantia medullaris of the suprarenals, and the possibility of the restoration of the reserves by noradrenalin. Male dogs were used in the experiments. The right suprarenal gland and the substantia medullaris of the left suprarenal gland were removed. The sympathetic innervation of the musculus retractor penis was used as the object of investigation. On the sixth day after the initial operation the abdominal cavity was opened and the sympathetic post-

Card 1/2

0976 0784

L 34738-66

ACC NR: AP6025124

ganglionic nerve stem in the area of the small pelvis was isolated. The nerves of the stem were crossed and placed on platinum electrodes. The abdominal cavity was then closed. A second incision was made in the perineum and the tendinous end of the musculus retractor penis was exposed and connected with a recorder of a kinematograph. Reserpine was introduced into one of the arteries at the root of the penis. The experiments established that the extirpation of the substata medullaris of the suprarenals and the administration of reserpine halts the process of the transmission of excitation from the adrenergic nerve to the smooth muscle, probably as a result of the exhaustion of the mediator reserves; synaptic transmission is usually restored about four hours after the administration of the reserpine; restoration of synaptic transmission is prevented by the protracted stimulation of the sympathetic motor nerve following the administration of the reserpine; noradrenalin in small doses does not hasten the restoration of the synaptic transmission of excitation; in large doses, however, it restores neuromuscular transmission of excitation almost immediately after its administration; apparently the axonal endings are capable of absorbing and utilizing noradrenalin as a mediator when it is present in the blood in large concentrations. TITLE: Phenomenon of secondary tunneling in GaSb

SOURCE: Fizika tverdogo tela, v. 8, no. 7, 1966, 2218-2221

TOPIC TAGS: gallium compound, antimonide, volt ampere characteristic, tunnel diode, pn junction, temperature dependence, semiconductor research

ABSTRACT: The authors investigated the volt-ampere characteristics of tunnel junctions produced with p-GaSb as the basis, at different temperatures, for the purpose of explaining the nature of the secondary peaks on the volt-ampere characteristic. Inverted diodes were produced from single-crystal p-GaSb doped with zinc. The p-n junctions were produced by fusing an alloy of 98% Sn plus 2% Te in vacuum. The volt-ampere characteristics were plotted at the different temperatures using direct current and a null method. The secondary peaks were observed in the voltage range 0.28 - 0.32 v at room temperature and are attributed to the presence of deep levels in the semiconductor, caused by uncontrolled impurities and defects and allowing the carriers to tunnel through the p-n junction. The observed temperature dependence of the position of the secondary peaks is attributed to the temperature dependence of the injection current, and not to a possible influence of the residual resistance of the diode. The author thanks G. B. Abdullayev for interest in the work and valuable remarks. Orig. art. has: 3 figures and 2 formulas.

PURPOSE: The publication is intended for scientific workers and specialists employed in enterprises where radioactive isotopes and nuclear radiation are used for research in chemical, geological, and technological fields.

COVERAGE: This collection of 133 articles represents the second volume of the Transactions of the Tashkent Conference on the Peaceful Uses of Atomic Energy. The individual articles deal with a wide range of problems in the field of nuclear radiation, including: production and chemical analysis of radioactive isotopes; investigation of the kinetics of chemical reactions by means of isotopes; application of spectral analysis for the manufacturing of radioactive preparations; radioactive methods for determining the content of elements in the rocks; and an analysis of methods for obtaining pure substances. Certain

TITLE: Ag^{110*} positron spectrum

PERIODICAL: Akademiya nauk SSSR. Izvestiya. Seriya fizicheskaya, v. 26,
no. 8, 1962, 1042 - 1045

TEXT: The positron spectrum was studied using a double-focusing β -spectro-
meter which gave a resolving power of 1.8% at a solid angle of 1.2% of 4π .
The Ag^{110*} source was supplied by thermal-neutron irradiation from metallic
silver of natural isotopic composition. Sources of 0.6 - and ~ 6 mg/cm²
thicknesses were used. The spectrum mainly consists of positrons produced
in internal conversions giving γ -quantum pairs with energies of 1380, 1480,
1500, and 1560 kev. In the hard part of the spectrum, it was possible to
separate out positrons derived from transitions at 1780 and 1930 kev.
Transitions with energies of 1650 and 1880 kev are supposed. The multi-
plicities of the most important transitions were determined from the ratio
of the pair conversion coefficient to the electron conversion coefficient

no. 1, 1963, 35 - 40

TEXT: Two rhenium isomers with the half lives of 13 and 64 hr were obtained in the reaction $Ta^{181}(\alpha, 3n)Re^{182}$ after chemical processing (purification) of the reaction product. These two isomers show positron emission during their $Re^{182} \rightarrow W^{182}$ decay, with intensities of $\sim 3 \cdot 10^{-3}$ and $5 \cdot 10^{-6}$ positrons per decay event, for the short and long-lived isomer, respectively. Analysis of the β -spectrum of the short-lived isomer by means of a Fermi graph showed two branches of β^+ -decay with threshold energies of 550 ± 20 kev and 1740 ± 20 kev and the relative intensities of $0.6 \cdot 10^{-3}$ and $1.8 \cdot 10^{-3}$ positrons per decay event. The total energy of the $Re^{182} \rightarrow W^{182}$ transition is 2860 ± 20 kev. The positrons are due mainly to internal

Investigation of manganic-ferrous garnet. S. T. Badalov, *Doklady Akad. Nauk Uzbek. S.S.R.* 1949, No. 12, 22-6. — A detailed investigation was made of garnet taken from pegmatite veins, including a complete chem. analysis. By disregarding negligible amts. of pyrope and grossularite, it is possible to consider the compn. of the mineral on the basis of manganic-ferrous compds. A heating curve was made, and it showed 2 clearly defined exothermic effects. One, at 500°, corresponds to oxidation of ferrous oxide. The other, at 850°, refers to oxidation of manganous oxide. Another indication of oxidation was that, during heating, the color of the mineral changed from light rose to cinnamon. X-ray powder data are given. G. S. M.

Vanadium-containing tourmaline and garnet. S. T. Badalov. *Zapiski Vsesoyuz. Mineral. Obshchestva (Mem. soc. russe mineral.)* 80, 212-13(1951).—Both V-bearing minerals are observed in the contact zone of quartz veins with black V-contg. quartz-graphite hornfelses. (1) Tourmaline in thin brown needles d. 3.028, neg., uniaxial, $\gamma = 1.635 \pm 0.003$, $\alpha = 1.618 \pm 0.001$, $\gamma - \alpha = 0.017$, strong pleochroism: γ -brown; α light-greenish. Chem. analysis: SiO₂ 37.73, B₂O₃ 8.08, Al₂O₃ 31.88, V₂O₅ 5.70, MgO 8.90, FeO 0.82, Na₂O 1.70, K₂O 0.53, CaO 2.14, H₂O 1.67, and F 0.13. The V₂O₅ replaces Al₂O₃; the x-ray diagram is practically identical with that of ordinary tourmaline. (2) Garnet, in dodecahedra of 1.5 to 2 mm. diam., of dark-green color, with strong zonal structure: dark green in the central, nearly colorless in the exterior parts, d. 3.53; $n = 1.741$. Chem. analysis: SiO₂ 39.16, Al₂O₃ 16.39, V₂O₅ 1.52, Fe₂O₃ 3.13, Cr₂O₃ 1.01, CaO 31.96, and MgO 3.30 corresponding to 60.49 grossularite, 15.10 V-garnet (Ca₃V₂Si₂O₁₁, with 30% V₂O₅), 11.05 pyrope, 10.01 andradite, and 3.35 uvarovite. Spectral analysis showed that the dark-green central parts are particularly high in V and Cr. Both minerals originate from a concn. of V from the surrounding country rock (hornfels) under postmagmatic soln. conditions.

"Influence of Medium on the Composition and Form of Calcite Crystals,"
Dokl. AN UzSSR, No 3, 39-43, 1953 (Uzbekistani resume)

The authors have studied the various crystalline forms of calcites which occur under various geological and physicochemical conditions from one of the deposits of Central Asia. The composition of the studied calcites, their color, specific gravity are due, up to a certain extent, to the composition of the containing rocks in which the crystallization of the mineral occurs. The form of the calcite crystals almost does not depend on their composition, but, in considerable degree, is due to the peculiarities of the chemism of the medium in which they are formed.

Thermal study of serpentized limestone. S. T. Badalov, M. I. Ismailov, and E. E. Rabatova; *Zapiski Ucheb. Vsesoyuz. Mineralog. Obshchestva, Akad. Nauk Uzbek. S.S.R.* 1954, No. 5, 45-9. — On heating synthetic mixts. of serpentine and calcite, thermograms were obtained which were similar to those from natural serpentized limestone. The temp. curve can be interpreted quantitatively ($\pm 5-8\%$) in terms of mineral compn. only by comparing the relative areas of the endothermal deflections with those of standards. The precise temps. at which these deflections occur are of secondary importance. The effect of impurities in calcite is to lower the temp. of endothermal reaction assocd. with its calcination. Impurities in serpentine diminish its exothermal peak (forsterite formation) and the temp. of its endothermal decompn. The calcite-serpentine

synthetic mixts., used as standards, contained 0-100% calcite. The serpentized limestone samples varied from 20% serpentine, 80% calcite to 20% calcite, 80% serpentine.

Data on Hemihydrate

The authors distinguish the following genetic types of deposits of hemihydrate: hemihydrates of sedimentary origin (in marine and lake-brackish deposits); hemihydrates formed in soil under desert conditions in gypsum-thenardites, carbonate, and halide saliniferous crustations; hemihydrates formed during the dehydration of gypsum on the surface yields or under the action of sulfuric acid in sulfur deposits; hemihydrates formed during hydration of sedimentary or hydrothermal anhydrite; hemihydrates as intermediate variety in the transition of gypsum into anhydrite at great depths. Deciphering of the Debye-grams and thermograms of the hemihydrates indicate the presence in them of admixtures of gypsum and anhydrite. (RZhGeol, No. 5, 1955) Tr. Sredneaz. un-ta. USSR:

1. Occurrence of hydrothermal anhydrite in Central Asia.
S. T. Badalov (Inst. Geol. Acad. Sci. Uzbek. S.S.R.)
~~Zapiski Vsesoyuz. Mineralog. Obshchestva~~ 63, 245-6 (1954).

A peculiar paragenesis of anhydrite with tourmaline, sphalerite, pyrite, chalcopyrite, galena, fluorite, and calcite is observed in veins in which the anhydrite is distinctly older than the sulfide minerals. The occurrence is observed in sycite, in contact with granodiorite porphyries. Circulating surface waters have changed some anhydrite to gypsum even down to depths of 300-350 m., but this hydration is incomplete and only a few cm. deep; the sulfides are not changed at all. The somewhat reddish violet anhydrite crystals show a mother-of-pearl luster on the cleavage planes; hardness 3 1/2; $d = 2.043$; $\gamma = 1.012$; $\alpha = 1.570$; optically pos. The spectral analysis of the remarkably pure mineral shows only Mg, Sr (up to 1%); Si, Cu, Fe

(up to 0.1%); Zr, Ti, Ba (up to 0.01%); Pb, Mn (about 0.001%). The occurrence of pyrite in sharp small pentagon-dodecahedra on the cleavage planes of anhydrite, or small veinlets of pyrite and chalcopyrite in the anhydrite, is highly interesting; green tourmaline is usually observed on the walls of the anhydrite veins and fluorite is found in their central parts.

The Origin of Calamine (O genezise kalamina)

PERIODICAL: Zap. Uzbekist. otd. Vses. mineralog. o-va, 1955,
Nr 8, pp 161-165

ABSTRACT: During study of a polymetal deposit, it was discovered that Zn occurs principally as calamine in the zone of oxidation. The crystals have an elongated tabular form and vary widely in size, from 0.01 mm to 2 to 3 mm and even to 5 to 6 mm in length, up to 3 to 4 mm in width, and up to 1 to 2 mm in thickness. Of the simple forms, the pinacoids $[100]$ and $[010]$, the prisms $[301]$ and $[031]$, the rhombic prism $[110]$, and the basal pinacoid $[001]$ were identified. The calamine is

TITLE: Some Results of the Study of Hydrothermal Helvite
(Nekotoryye rezul'taty izucheniya gidrotermal'nogo
gel'vina)

PERIODICAL: Zap. Uzbekist. otd. Vses. mineralog. o-va, 1956, № 10,
pp 59-67

ABSTRACT: The paper presents some of the results of the mineral-
geochemical investigations of helvite of hydrothermal
origin. Six different types of helvite occurrences were
identified. 1) Polymetal vein stockworks, consisting of
sphalerite, galena, and helvite. Very frequently the
helvite is included in coarse crystals of sphalerite. 2)
Quartz-helvite mineralization with pyrite, in zones of
crushing among the polymetal ores. The helvite occurs
around ore fragments, which serve as centers of crystal-
lization. Quartz mineralization occurred in several

Card 1/2

Some Results of the Study of Hydrothermal Helvite

15-1957-10-14073

stages, the last of which is barren everywhere. 3) Calcite-amethyst-helvite vein stockworks. The helvite forms bands between calcite and amethyst. This relationship indicates a sharp change in the composition of the hydrothermal solutions; at this stage it now contains sulphurous sulfur. 4) Helvite mineralization in tectonic zones containing talc. Here also the helvite occurs in ore breccia, cemented by talc. The helvite crystals have normal terminations and crumble easily. 5) Quartz-chalcedony-helvite mineralization in zones of crushing. The helvite occurs in quartz, chalcedony, and talc. 6) Helvite mineralization in chalcedonic formations which contain almost all the ore minerals characteristic of the polymetal mineralization. The types of helvite occurrences listed are principally distinguished by the accompanying minerals. They are all younger than the chief stage of polymetal mineralization.

Title : Data on Geochemistry of Vanadium

Orig Pub : Tr. In-ta geol. AN UzSSR, 1956, No 12, 65-73

Abstract : Spectral analyses were made of more than 34 specimens of minerals of eruptive and sedimentary-metamorphic rocks of a Central Asian district. The district is formed by a metamorphic sandstone-schist Upper Silurian series with faults of granitoid rocks of Varissian age. Coefficient of concentration (V content in granodiorites is taken as the unit) is within the following limits: in contact-metamorphic rocks 10-500; granites, quartz-diorites, lamprophyres and others < 1-10; biotites < 1-250; muscovites 1-10, garnets, tourmalines and other minerals < 1-3000. The principal source of V are black quartz-graphite hornstones produced as a result of contact metasomatism from sedimentary-bituminous vanadium containing rocks. Accumulation of V took place in a reducing medium during deposition of organic matter, which was converted into quartz-

1/2

Abs Jour : Referat Zhur - Khimiya, No 4, 1956, 11504

graphite hornstone during subsequent processes of metamorphism. Almost all the intrusion assimilated V is concentrated primarily in biotite and partially in muscovite, and as a rule is not concentrated in any of the subsequent phases, except small hydrothermal veins, which contain at sites of their passage through hornstone rare V-bearing minerals: roscoelite, tourmaline, garnet etc.

AUTHOR: Badalov, S. T.

TITLE: New Data on ThauMasite From Central Asia (Novyye dannyye o taumasite iz Sredney Azii)

PERIODICAL: Tr. Sredneaz. un-ta, 1956, Nr 82, pp 19-24

ABSTRACT: The rare mineral thauMasite has been discovered in lead-zinc deposits in the Kuraminskiy Mountains, where it forms veins and networks in the host rocks. Dark thauMasite of an earlier generation is cut by veinlets of white thauMasite. The early thauMasite is characterized by near-vein alteration and calcium metasomatism, whereas the boundaries between the later thauMasite and the host rock are sharp, and no metasomatism is present. The luster of the thauMasite is silky (in the fibrous varieties) to dull (in the fine-

Card 1/2

Cent. Asian State U.

New Data on Thaumasite (Cont.)

15-57-7-9407

grained varieties). The hardness is 3, the specific gravity 1.901. The indices of refraction are Ng 1.508 and Np 1.469. The chemical composition is SiO₂ 10.38 percent, CaO 26.40 percent, MgO 0.47 percent, SO₃ 12.55 percent, CO₂ 7.33 percent, H₂O 42.87 percent. Two effects are observed on the thermal curves: an endothermic effect from between 800 and 100° to 300° (loss of water) and an exothermic effect from between 600° and 700° to 800° (formation of Ca₂SiO₄). Very weak exothermic effects on one thermal curve (at 890° and 1120°) are associated with the formation of free CaSO₄. The elimination of CO₂ occurs gradually and is not reflected in the thermal curves. X-ray studies of thaumasite and its roasting by-products verified the formation of Ca₂SiO₄ and CaSO₄. The author concludes that the thaumasite is of hydrothermal origin, with surface solutions contributing in part. The presence of this mineral indicates the culmination of an ore process the earlier stages of which should invariably be accompanied by the separation of anhydrite and calcite.

TITLE: A Monticellite Skarn From Central Asia (Monticellitovyy skarn iz Sredney Azii)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol. 121, Nr 5, pp. 897-900 (USSR)

ABSTRACT: Monticellite, sperrite, and melilite have been known in Central Asia (Srednyaya Aziya) since 1950. The former forms in all known cases both alone and also with the complex of its paragenetic minerals (of the two last-mentioned ones) considerable accumulations of metamorphosed minerals which are bound to the contact zone between eruptive and carbonate rocks. Table 1 shows the physical properties of monticellite from Gavasay (Namangan area, Uzbek SSR = Namanganskaya oblast', Uzbekskaya SSR) and from Almalyk. The latter forms small roundish grains of 0,1 to 1 mm of size, without crystalline shape; the monticellite grains from Gavasay are angular, of irregular shape, up to 0,1 mm of size. Table 2 shows chemical analyses with a conversion to mineral components to-

Card 1/3

SOV/20-121-5-36/50

gether with comparing data from other sites. The first author took a radiogram in the Radiometric Laboratory of the Institute of Geology of the AS, Uzbek SSR (Institut geologii Akademii nauk UzSSR). Table 3 shows the results of his interpretation. They confirmed the composition of the mineral as monticellite from Almalyk. Moreover, sperrite is found in the skarn from Gavasay. It forms crystals of 0,05 to 0,1 mm of size, of irregular shape, which develop at the cost of the monticellite grains. The mineral of the melilite group forms small angular crystals which often have an almost square cross-section. The formation of the monticellite-skarn is genetically bound to the contact-zone between eruptive rocks of middle to basic composition and to dolomites (Almalyk) or dolomitized lime (Gavasay). Here, like elsewhere, the process has taken place under the participation of postmagmatic solutions (Ref 6). It follows from table 4 that CO₂-gas escaped during the formation of monticellite skarn and that kieselguhr penetrated into the solution. There are 4 figures, 1 table, and 12 references, 10 of which are Soviet.

TITLE: On the Geochemistry of Cadmium in the Almalyk and Altyn-Topkan Ore Deposits of Karamazar (K geokhimii kadmiya v Almalykskom i Altyn-Topkanskom rudnykh polyakh Karamazara)

PERIODICAL: Geokhimiya, 1959, Nr 4, pp 328 - 335 (USSR)

ABSTRACT: The cadmium tenor were determined by V. A. Moskvitina, P. L. Prikhid'ko and V. V. Prasalova polarographically and chemically in the laboratory of the trust Uzgeolrazvedka, and in the laboratory of the Institut geologii AN UzSSR (Institute of Geology AS UzSSR). Further comparison values from other deposits of the USSR and foreign countries were used. The investigations give the following data: Cadmium tenor in zinc blends of the copper-molybdenum mineralization of Almalyk (Table 1), cadmium tenor in zinc blends of other deposits (Table 2), cadmium and iron tenor in zinc blends in the polymetallic mineralization of Zapadnyy Karamazar and comparison values from other districts of the USSR (Table 3), cadmium tenor in tetrahedrites of Karamazar and Rudnyy Altay (Table 4), cadmium tenor in minerals of the oxidation zone

(Table 5). From this the following results: Under hypogene conditions cadmium is enriched in zinc blendes, less in zinc tetrahedrite; with decreasing temperature the cadmium tenor of the zinc blendes increases. The cadmium tenor does not depend there so much on the iron tenor of the zinc blendes as on the type of the deposit and the paragenesis. The comparatively high cadmium tenor of the zinc tetrahedrites has hitherto not been considered; an investigation of other sulfidic zinc ores, such as chalcopyrite, bornite, enargite, and others would be desirable in this connection. In the oxidation zone cadmium is found in the smithsonite and in minute quantities in the calcite. In other zinc minerals cadmium is practically not found. There are 5 tables and 24 references, 20 of which are Soviet.

Voprosy mineralogii, geokhimi i genezisa mestorozhdeniy redkikh elementov
(Problems in Mineralogy, Geochemistry, and Deposit Formation of Rare Elements)
Moscow, Izd-vo AN SSSR, 1960. 253 p. (Series: Its: Trudy, vyp. 4) Errata
printed on the inside of back cover. 2,200 copies printed.

Chief Ed.: K. A. Vlasov, Corresponding Member, Academy of Sciences USSR;
Resp. Ed.: V. V. Lyakhovich; Ed. of Publishing House: L. S. Tarasov;
Tech. Ed.: P. S. Kashina.

PURPOSE: This book is intended for geologists, mineralogists, and petrographers.

COVERAGE: This is a collection of 23 articles on the formation, geology,
mineralogy, petrography, and geochemistry of deposits of rare elements in
Siberia and [Soviet] Central Asia. The distribution and characteristics of
rare elements found in these areas as well as some quantitative and qualitat-
ive methods of investigating the rocks and minerals in which they are found,

or with which they are associated, are discussed. Two articles present an economic investigation of the possibilities of industrial extraction and utilization of celenium, tellurium, and hafnium. No personalities are mentioned. Each article is accompanied by references.

TABLE OF CONTENTS:

GEOCHEMISTRY

Garmash, A. A. Peculiarities in the Distribution of Rare Elements in Polymetallic Deposits of the Zmeinogorsk Region of Rudnyy Altay	3
Semenov, Ye. I. On the Content of Lithium and Rubidium in Minerals of Alkaline Pegmatites of the Lovozerskiy Massif	20
Badalov, S. T., and S. Ruzmatov. On the Geochemistry of Selenium and Tellurium in the Ore Deposits of Almalyk	24
Gorokhova, V. N. On the Content of Rhenium in Molybdenites of the Kadzharan Copper-Molybdenum Deposits	28
