TOPIC TAGS: chloroalkyldisilylethane, acetoxy silane derivative, silanol, siloxane, organosilicon compound

ABSTRACT: The authors obtained the corresponding acetoxy derivatives in reactions of mono- and dichloroalkyldisilylethanes with acetic anhydride (heating to the b. p. of acetyl chloride, yield 88%). Hydrolysis of monochlorides of the 1,2-disilylethane series (1N NaOH) yielded the corresponding silanols. Hydrolysis of 1-tributylsilyl-2-methylbutylchlorosilylethane yielded 64% silanol and 19% siloxane. Dehydration (concentrated HCl) of the synthesized silanols converted these to siloxanes. The acetoalkyldisilylethanes were colorless mobile liquids, soluble in numerous organic solvents. The

TOPIC TAGS: boron, boron compound, organoboron compound, isoprene, diene synthesis

ABSTRACT: The reaction of diborane with isoprene and cis- and trans-piperylene was investigated. The study is an extension of previously published work of the authors (Dokl. AN SSSR (v pechaty)). The experimental procedure followed here is described by B. M. Mikhaylov, A. Ya. Bezmenov, L. S. Vasil'yev, and V. G. Kiselev (Dokl. AN SSSR 155, 141, 1964). A reaction mechanism is proposed, and the reaction yields and degree of monohydroboration are tabulated. The experimental results are compared with literature values presented by G. Zweifel, K. Nagase, and H. C. Brown (J. Amer. Chem. Soc. 84, 183, 1962). It was found that the degree of hydro-

TITLE: Wide-band Transistor Preamplifier

PERIODICAL: Pribery i tekhnika eksperimenta, 1960, No. 6,
pp. 56 - 57

TEXT: The circuit of Fig. 1 is to match the high output resistance of the photomultiplier of a scintillation gamma-ray spectrometer with the low characteristic impedance of a coaxial cable. The great attraction of the transistor circuit is its freedom from microphony. The two transistors Π_3 and Π_4 form an emitter follower analogous to the White circuit, well known for tubes. The base current of the lower transistor, whose high AC resistance constitutes the emitter load of the upper transistor, is stabilized by the silicon stabilistor Π_5 . The transistors are alloy-diffusion types $\Pi-402$ (P-402) or $\Pi-403$ (P-403). The load on the amplifier is a 150 ohm resistor connected by 20 m of coaxial
Card 1/4

E041/E335

Wide-band Transistor Preamplifier

cable. The overall gain, including the cable, is 0.92. The input resistance of the amplifier is 250 k Ω in parallel with 16 pF. The output resistance of the amplifier is 8.6 Ω . The circuit will handle without distortion pulses between +0.4 and -3.5 V, at temperatures up to +70 $^{\circ}$ C. The rise time does not exceed 2×10^{-8} sec with a very small overshoot. Fig. 3 shows the effect on the rise time of the output signal ($\tau_{\phi} \cdot 10^{-8}$ μ s) on the capacitance (C_H , μ F) connected in parallel with the load resistor (150 ohm); the rise time of the input signal is 3.8×10^{-8} sec. To obtain the best results the transistors are carefully selected. Π_1 and Π_2 should have high β , Π_3 can have an average β while Π_4 is not critical. The diode Δ -810 (D-810) can be changed

TITLE: Heat of formation of methoxyboracyclopentane and methyl di-n-butylboric acid

SOURCE: AN SSSR. Doklady, v. 166, no. 1, 1966, 103-105

TOPIC TAGS: heat of formation, boron compound, boric acid, *heat of polymerization*

ABSTRACT: The ¹¹³heat of combustion, ΔH_c , of these compounds was determined calorimetrically, using a precise water calorimeter, and heats of formation were calculated subsequently. Accuracy of determination was $\pm 0.02\%$. The combustion products, CO_2 and H_3BO_3 , were determined gravimetrically or by base titration in the presence of mannite, respectively. Among the compounds investigated, the $(n-C_4H_9)_2BOCH_3$ burned more completely than the others. The determined ΔH_c^0 at 298.15°K were -911.7 ± 0.6 kcal/mole for liquid $\square B-OCH_3$ and -1590.9 ± 0.8 kcal/mole for liquid $(n-C_4H_9)_2BOCH_3$. The ΔH_c of polymerized $\square BOCH_3$ was also determined and was -9296.2 ± 1.0 cal/g. Thus, the calculated heat of polymerization was ~ -1 kcal/mole. The polymer was prepared by keeping the monomer in sealed ampules for 3 to 8 months at room temperature. It was a clear

TITLE: A turbulent jet of air heated to 4000 °K

PERIODICAL: Izvestiya Akademii nauk SSSR, Otdeleniye tekhnicheskikh nauk, Energetika i avtomatika, 1961, No.4, pp. 42-45

TEXT: Non-isothermal jets with considerable temperature gradients which are encountered in boiler furnaces and gas-turbine combustion chambers have been little studied. Previous work on the subject, which is briefly reviewed, makes various assumptions which are still not fully justified experimentally for a wide range of ρ_2/ρ_1 where ρ_2 is the air density in the initial part of the jet and ρ_1 the density of the surrounding medium. The present work describes investigations on a free submerged jet of air heated in an electric arc heater to a temperature of 4000 °K, for which the density ratio $\rho_2/\rho_1 = 14$. The air was delivered tangentially to an electric arc chamber with water-cooled electrodes and was discharged through a hollow electrode with an internal diameter of 30 mm. The temperature and total pressure were measured at various sections of the jet. The measurement
Card 1/ 6

2750

A turbulent jet of air heated to 4000°K S/024/61/000/004/008/025
E194/E155

technique is briefly described. The following notation is used:
 the relative velocity head on the axis of the jet,
 $p = \rho_m u_m^2 / \rho_0 u_0^2$ the relative excess temperature
 $v = (t_m - t_a) / t_{cp} = t_a$ Figs. 2 and 3 give graphs of p and v
 as functions of x/d (the distance between the section considered
 and the discharge from the nozzle). Curves are also given for very
 moderate heating when the density ratio is approximately unity.
 It will be seen that the distribution of velocity head along the
 axis of the jet is not the same when the density ratio is 14 as
 when it is unity. Hence one of the assumptions made in previous
 work is incorrect. Fig. 3 also shows a curve plotted by the
 following formula:

$$\eta = \frac{\int_0^b \rho u du}{\int_0^b \rho dy} \quad (3)$$

derived by G.N. Abramovich (Ref. 2: Teoriya turbulentnykh struy
 (The Theory of Turbulent Jets), Fizmatgiz, 1960). It will be
 seen that the calculated length of the initial section is shorter
 than is found experimentally, and the calculated temperature drop
 Card 2/ 6

27654

A turbulent jet of air heated to 4000°K S/024/61/000/004/008/025
E194/E155

is more rapid than the experimental. The reasons for this are discussed. The position of the jet boundary was determined in three ways, giving the results plotted in Fig.4, where curve (a) corresponds to formula (3), curve (b) to the assumption that the width of the zone of mixing does not depend on the degree of heating, and (c) to the assumption that the typical velocity is given by the following expression:

$$u = \frac{\int_0^b \rho u^2 dy}{\int_0^b \rho dy} \quad (4)$$

This expression is recommended by B.F. Glikman (Ref.6: Izv.AN SSSR, OTN, Energetika i avtomatika, 1959, No.1) for high values of density ratio. It will be seen that the actual width of the jet lies below the value given by formula (3) and near to the other two curves. Figs. 5 and 6 give dimensionless velocity distribution $U = u/u_m$ and excess temperature $\theta = (t - t_a)/(t_m - t_a)$ at various sections. Curves are also given plotted according to the following formulae:

Card 3/ 6

A turbulent jet of air heated to 4000°K ⁸⁷⁸⁵⁰ S/024/61/000/004/008/025
E194/E155

$$U = \frac{u}{u_m} = \left[1 - \left(\frac{y}{b} \right)^{3/2} \right]^2 \quad (5)$$

$$\frac{t - t_a}{t_m - t_a} = \sqrt{\frac{u}{u_m}} \quad (6)$$

It will be seen that expression (5) satisfactorily describes the velocity distribution, whilst the temperature distribution lies between the curves of expressions (5) and (6) but nearer to (5). There are 6 figures and 6 references: 5 Soviet and 1 English. The English language reference reads:

Bezmozgin, E.S.

2707. REACTIVITY OF SHALE COKE IN RELATION TO BREAM. Simolinikov, A.G. and Bezmozgin, E.S. (Trud. Vsesoyuz. nauch.-issled. Inst. Pererab. Gluk. (Proc. Inst. Treat. Shale, U.S.S.R.), 1955, (3), 66-71; abstr. in Ref. Zh. Khim. (Ref. J. Chem. Moscow), 1956, (6), 16985). The reaction of different shale cokes with steam was studied in a 20 mm quartz tube (in length, also of tar cokes from the pyrolysis of shale tar at 650 to 1100°C). It was established that low temperature shale coke produced in a rotary retort is the most reactive, and the tar coke the least with a reactivity similar to that of cokes; that the reactivity of chamber cokes does not depend much on the method of its subsequent treatment; that different shale cokes have similar reactivities, lying between those of coal cokes and peat coke. In order to diminish the carbon dioxide content of the gas produced, one is recommended to use the gas itself for cooling the coke in ovens with bottom outlets for the steam-gas mixture, and not steam as is usual, since at cooling curve temperatures around 750°C the carbon dioxide formed by dissociation of carbonates cannot be reduced to carbon dioxide at all completely. When the ovens have top outlets for the gas, steam cooling should increase the yield of water gas through further gasification of the coke taking place at high temperatures.

Bezmozgins

7

The effect of pyrolysis conditions on the hydrogen sulfide content of shale gases. E. S. Bezmozgin, A. S. Sinelnikov, and E. A. Latus. *Trudy Vsesoyuzn. Nauch.-Issledovatel. Inst. po Perarabotke Slanets*, 1958, No. 3, 72-5; Referat. *Dokl. Akad. Nauk*, 1958, Abstr. No. 50272. The H₂S content in the gas obtained from shale gases decreases with the lengthening of the pyrolysis zone and the increase of the zone temp.; it increases with the productivity acceleration of the chamber. It had been suggested that lowering the H₂S can be explained by its interaction with the mineral part of the shale coke. For clarification of this question comparative tests are performed by passing gas (contg. 0.6-1.3% H₂S) through shale coke, marble, porcelain, and lime. No H₂S absorption is observed when passing the gas through marble and porcelain while, when working with coke and lime even at 500°, less than 50% of the H₂S remains free, indicating a reaction with the mineral part of the coke. This applies mainly to the Cu and Mg oxides and also to their carbonates. With the temp. increase, the H₂S content decreases sharply, and at 900° is only 4-5%. N. Vasilov //

BEZIMU EQUIVALENTS

July

(Kaf. J. Chen, Moscow), 1955, (2), 4703). The completion of the
 carbonisation of semi-coke was studied under static and flow conditions in
 order to test the hypothesis that the reduction of carbon dioxide takes place
 for the most part within the pieces of coke, and to examine the possibility of
 also assessing quantitatively the gas emitted from the mineral portion. In
 the 700 to 1000°C temperature range under static conditions, simultaneously
 with a sharp increase in the yield of carbon dioxide (from 17.3 to 50.7 l./kg
 of semi-coke in 3 to 5 min/pieces) caused by intense dissociation of
 carbonates, there is an increase in the quantity of carbon monoxide (from
 4.5 to 75.5 l./kg) formed by reduction of carbon dioxide. In the 1000 to
 1100°C range both reactions take place at the same velocity. When a change
 is made from the small semi-coke to 40 min pieces, the concentration of carbon
 monoxide in the gas increases from 47.4 to 60% and that of carbon dioxide
 decreases from 45.2 to 28.6%. This indicates that the reduction of carbon
 dioxide takes place preponderantly inside the pieces of coke. This is
 confirmed by analysis of the solid residue after the completion of

1/2

4
0
0
0

Effect of MINERAL

carbonisation. Under flow conditions (with nitrogen blown through the layer of semi-coke) the concentration of carbon monoxide in the gas increases from 48.5% at 700 to 75.0% at 1100°C, while that of carbon dioxide decreases correspondingly from 41.8 to 7.7%. It is shown that in the 700 to 900°C temperature range the greater part of the carbon dioxide is emitted only under flow conditions, but at 900°C emission takes place also in the absence of these conditions, i.e. in a process with no blowing through. The blowing of an inert gas through incandescent shale coke instates the emission of an additional quantity of carbon dioxide formed by the reaction of carbon monoxide with the carbon in the coke. Generalizations are made about the simultaneous changes in the mineral and organic portions of the solid residue which take place during carbonisation in ovens and gasification in producers.

1221. HIGH TEMPERATURE DECOMPOSITION OF VOLATILE PRODUCTS FROM LOW TEMPERATURE CARBONIZATION OF PALEOGENE SHALES. Bezmozgim, L.S. and Sinelnikov, A.S. (Trud. Vsesoyuz. nauch.-issled. Inst. Pererab. Glan. (Proc. Inst. Treat. Shale, U.S.S.R.), 1955, (4), 92-99; abstr. in Ref. Zh. Khim. (Ref. J. Chem., Moscow), 1956, (16), 51659). A 15 mm quartz tube 1 m long had 300 mm of its length filled with shale and 400 mm with shale coke in 3 to 5 mm grains. With the time of contact between the steam-gas mixture and the incandescent coke constant at 8 to 9 sec and the temperature in the pyrolysis zone increasing from 700 to 1000°C the yield of gas increased from 0.36 to 0.62 cu.m/kg of shale, but the concentration of saturated and unsaturated hydrocarbons in it decreased, and likewise the calorific value of the gas. However the total yield of heat for a given quantity of shale increased. Increasing the contact time at constant temperature gave the same results. Variation in the composition and volume of gas from low temperature carbonization during pyrolysis was studied in a quartz tube filled with shale coke which had been carbonised up to the temperature of the experiment. The contact time in these experiments was 3 to 6 sec. at 700 to 1000°C. In every case there was an increase in gas volume (up to 60 to 70% at 900°) and in the hydrogen content of the gas (owing to pyrolysis of hydrocarbons). The presence of steam in the pyrolysis zone decreased the depth of pyrolysis of hydrocarbons and enabled hydrocarbon conversion reactions to develop.

PURPOSE: This collection of articles is intended for scientific, engineering and technical personnel in plants of the fuel and gas industry.

COVERAGE: The results of research and experimental work carried out

in 1957 and 1958 by the All-Union Scientific Research Institute for Shale Processing are summarized in this collection. The components of oil shale from various regions, their composition, position, and physical and chemical properties are reviewed. Along with the production of gas and oil shale, also discussed are the reactions of tar obtained in oil shale sealcoating, conversion of tar and the equipment used, hydrogenation of diesel fuel produced from oil shale, extraction of phenol, and purification of tar waters by anionite and formaldehyde. Most articles are accompanied by references. In addition, the book contains an annotated bibliography of 126 Soviet and non-Soviet works on the production and processing of oil shale from the Baltic Region. TITLE: Continuous action equipment for production of commercial hydrogen. ¹¹ Class 12,
No. 174174 ₂₇

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 17, 1965, 14

TOPIC TAGS: hydrogen, chemical plant equipment, manufactured gas

ABSTRACT: This Author's Certificate introduces continuous action equipment for production of commercial hydrogen from natural or mixed gas. The equipment is made in the form of two chambers for full conversion of hydrocarbon gases. The first chamber is filled with a catalyst or an inert packing material for conversion of hydrocarbon gases with heat supply. The second chamber is filled with a catalyst for conversion of carbon monoxide with water jacket cooling.

The state of calcium in the blood serum of normal and parathyroidectomized dogs. ALADAR HERNÁK. *Magyar Orvosi Hetk.* 33, 21-9(1932). -Klinke's findings were that the Ca in blood serum exists in 3 different forms: 10-20% of the total in an ionized state, 30-50% as a complex salt and the remaining 40% as a combination with proteins. According to H. the complex Ca can be extd. with various positively charged adsorbents as bone powder or BaSO₄. By these methods the total and complex Ca contents of the serum of normal and parathyroidectomized dogs were detd. Both the total and the adsorbable Ca decrease in the serum of parathyroidectomized dogs. There seems to be a proportionality between the symptoms of tetany and decrease of the complex Ca content. The production of the negatively charged complex, which is capable of holding Ca in soln., is diminished in parathyroic tetany. H. TAUBER

Relation between tetanus symptoms and the calcium and inorganic phosphorus content in the serum of parathyroidectomized dogs. A. Baumán (Magyar Orvosi Arch., 1932, 33, 253-262; Chem. Zentr., 1932, ii, 2977).—Strychnine convulsions raise the inorg. P of blood-serum in normal and in parathyroidectomized dogs. The increase comes from the contracted muscles. In tetanus the creatine-P of muscle decreases, whilst the inorg. P increases. The Ca concn. in blood-serum decreases in tetanus convulsions, but increases in those produced by strychnine.

Negative inotropic action of the trichloroacetic acid extract of the subauricular glands during rest and during irritation of chorda tympani. ALADAR BRZNAK. *Magyar Biol. Kutató Intézet Munkái* 3, 182-3 (in German 184-6) (1932). -- During rest both right and left glands contain some substance of neg. inotropic influence equiv. to about 0.02 mg. % of acetylcholine. Expts. with 10 dogs in 2 groups showed that the neg. inotropic influence of the gland ext. increases during an irritation of chorda tympani for 30 min., reaching a value equal to 0.2 mg. % acetylcholine. This demonstrates that during irritation significant amts. of a new substance are formed which were not present previously. S. S. DE FINALY

Beznak A. B. L., Beznak M. and Hajdu I. Institute of Physiol. of the Peter Pazmany University, Budapest, Hungary The growth and the food and water consumption of the resting or exercising albino rat on diets containing various amounts of fat and a reduced quantity of vitamin B1 Hungarica Acta Physiologica 1947, 1/2-3 (35-51) Graphs 2 Tables 3

On a synthetic diet containing a minimum amount of thiamine, growth was stunted if its fat content (sunflower seed oil) was 3 per cent; it was normal and proportional to the fat content at 8 per cent, 16 per cent, and 32 per cent. On forced exercise for 28 days, growth was resumed in the 3 per cent fat group, and a transient loss in body weight (maximum 8 per cent) proportional to the fat content of the diet was a slight increase in growth. During the resting period after exercise the velocity of growth was greatly increased in all groups. Food and water consumption were in rest inversely proportional to the fat content of the diet. During exercise food consumption increased in the 3 per cent and decreased proportionally to the fat content on the diets rich in fat. Water consumption also increased during the second half of the exercise period or later. Efficiency of growth (growth x 100/food consumption) was proportional to the fat content of the diet. Growth and food consumption were not correlated. It is suggested that the stunted growth of the resting animal is due to an inadequate synthesis from some carbohydrate intermediate of some semi-essential fatty acid, consequential to the low fat and thiamine content of the diet.

The distribution of lethal sensitivity to histamine in normal and histamine pretreated guinea pigs. Aladar H. L. Heanok, Zoltanna Gáspár Rády, and Arisztid Gy. H. Kovach. *Arch. Biol. Hung.* 17, 202-75 (1972). The av. lethal dose of histamine for normal female guinea pigs is 150 γ for 180 g. of body wt., for normal males 240 γ . The so-called characteristic histamine curves detd. on normal guinea pigs and those pretreated with low doses of histamine showed that the curve for the latter loses its normal shape and shifts toward the positive. Some guinea pigs developed an increased resistance while the sensitivity of others remained unchanged. Approx. the same results were obtained if histamine treatment was carried out with doses considerably below the min. lethal dose for about 3 weeks or with doses increasing rapidly (in 1 week) to the level of the lethal dose range. The mechanism of the increase in resistance against lethal doses of histamine developed by previous injections of small histamine doses. Aristidyl, B. Kovach, Aladar B. L. Beznák, and Zsuzsanna Gaspar Rády. *Dokl. Akad. Nauk Hung.* 17, 278-303 (1972). O₂ and CO₂ were determined in the blood of 37 male guinea pigs of about 600 g body wt. under various kinds of histamine treatment. Normal values were 10.6-19.7% O₂ and 27.2-38.7% CO₂ in carotid blood, 0.18-1.26% O₂ and 48.8-65.0% CO₂ in normal animals killed by histamine treatment, 0.96-1.60% O₂ and 33.2-65.1% CO₂ in nonresistant histamine-killed animals, and 4.88-16.20% O₂ and 31.1-40.1% CO₂ in resistant animals surviving histamine-treatment. The cause of resistance seems to be a better oxygenation due to a decreased contraction response of the broncho- and vaso-constrictor muscles to the same level of histamine in blood. The histamine content of blood plasma at the peak of intoxication symptoms following subcutaneous injections of a lethal dose was, on an av., 4.65 μ cc. in normal guinea pigs, 2.45 in nonresistant histamine-treated animals, and 3.91 in resistant histamine treated animals. The lactic acid content of the blood of normal animals was 32 mg. % against 40 mg. % for histamine-treated guinea pigs. The most probable explanation of the mechanism of increase in resistance to histamine intoxication is an inhibiting effect on broncho- and vaso-constrictor muscles. 31 references. István Fényi

The effect of prolonged administration of *l*-ascorbic acid and *d*-gluconic acid on the body weight and food, water, and salt-solution consumption of albino rats. Aladár B. I. Beznák, Margit Beznák, and Zsuzsanna Gaspar-Rády. 1948. *Biol. Hung.* 17, 294-308(1947).—Male albino rats were given a diet consisting of wheat, rye and corn 25-25, casein 15, butter 3.5, MacCollum salt mixt. 4.0, and cod liver oil 1.3%, plus measured amts. of tap water and of a 1.0% aq. soln. of NaCl. Three groups were formed: Group 1 received daily 20 mg. *l*-ascorbic acid in 0.2 cc. distd. water through a stomach tube, group 2 20 mg. *d*-gluconic acid in 0.2 cc. distd. water, and group 3 only 0.2 cc. distd. water. Data of body wt. showed that neither the rule of Rubner nor that of Lusk-Wilson is valid for the velocity of growth. Among the animals with large suprarenal glands there were more which drank less salt soln. than among those with small glands. A definite correlation was found between the size of suprarenal glands and growth efficiency. Variations in consumption of salt soln. and water showed no relation. Both *l*-ascorbic and *d*-gluconic acids increased the av. growth by 11.5% and effected in identical manner the consumption of food, salt soln. and water. These effects seem not to be connected with the antiscorbic effects, but only with the acid groups of the investigated compds. 15 references. I. F.

The effect of histamine on body temperature of normal and of histamine pretreated guinea pigs and the mechanism of the changes. Aladar B. L. Bernák, Aristid Gy. H. Kovách, and Zsuzsanna Csápp-Rády. *Arch. Biol. Hung.* 10, 349-52 (1948).—Forty female and 77 male guinea pigs were divided into groups. Some groups received pretreatment of subcutaneous histamine injections twice daily starting with 5 γ /100 g. body wt., increased daily by 10 γ until the 6th day, and then maintaining the daily dose of 55 γ until the 21st day. Measurement of the rectal temp. of untreated guinea pigs showed that subcutaneous and intraperitoneal histamine injections caused a monophasic gradual fall or a biphasic reaction consisting of an initial increase followed by decrease. In the group of pretreated animals the biphasic reaction was observed and the total max. temp. decrease was smaller than in untreated ones. Measurement of the temp. in the right and left halves of the heart, in the rectum, on the skin of the chest, and of the abdomen during histamine shock showed a decrease in heat production. The temp. of the heart, rectum, and skin slowly decreased in the guinea pig tied supine in a cotton-wool covering. This diminishing was enhanced if the air breathed contained less O₂ and was inhibited if it contained more O₂. The temp. changes in histamine shock are to a large extent due to changes in the O₂ supply of the blood in the lungs. The heat-regulating center of the organism does not take part in these changes. The biphasic inverse reaction seems to be due to decreased bronchoconstriction combined with a secondary compensatory hyperventilation. I. Finaly

FEZNAK M. Institute of Physiol. of the Peter Pazmany University, Budapest, Hungary
The growth and the food and water consumption of the resting or exercising albino rat on diets containing various amounts of fat and reduced quantity of vitamin B₁
Hungarica Acta Physiologica 1947, 1/2-3 (35-51) Graphs 2 Tables 3

On a synthetic diet containing a minimum amount of thiamine, growth was stunted if its fat content (sunflower seed oil) was 3 per cent; it was normal and proportional to the fat content at 8 percent, 16 per cent, and 32 percent. On forced exercise for 28 days, growth was resumed in the 3 per cent fat groups, and a transient loss in body weight (maximum 8 per cent) proportional to the fat content of the diet was a slight increase in growth. During the resting period after exercise the velocity of growth was greatly increased in all groups. Food and water consumption were in rest inversely proportional to the fat content of the diet. During exercise food consumption increased in the 3 per cent and decreased proportionally to the fat content on the diets rich in fat. Water consumption also increased during the second half of the exercise period or later. Efficiency of growth (growth x 100/food consumption) was proportional to the fat content of the diet. Growth and food consumption were not correlated. It is suggested that the stunted growth of the resting animal is due to an inadequate synthesis from some carbohydrate intermediate of some semi-essential fatty acid, consequential to the low fat and thiamine content of the diet.

Hungarian Biological Res. Inst., Tihany The distribution of the different protein fractions in normal and hypertrophied cats' hearts *Archiv. Biologica Hungarica* 1947, 17 (102-112) Pages 6

Left ventricular hypertrophy was caused in 12 cats of both sexes by destruction of the aortic valves by means of a rod pushed down through the left carotid. Comparison with 12 normal cats of the same sex, age and weight distribution showed with statistical certainty that the total heart weight, the heart weight/kg. body weight, left ventricle + septum weight, left ventricle + septum weight/body weight, left ventricle + septum/right ventricle values had all increased. Dry matter, total N, extractable N, its myosin, globulin, myogen and non-protein N fractions were determined by the H. H. Weber and K. Meyer method (1933). The non-extractable N was determined in three fractions: collagen, fluid N, remaining N. In three cases all these determinations were carried out on the psoas muscle also. The hypertrophied heart muscle contains the same percentage of dry matter as does the normal one. Its N content is 7% more than that of the normal. The distribution of the different fractions remains the same with the exception of the non-extractable remaining N, which tends to decrease. Compared to the skeletal muscle the heart contains somewhat less N, and a smaller part of the heart's N content is extractable.

The autonomic innervation of the heart in regulating the blood sugar. Istvan Hajdu, Margit Bernák, and Zsuzsanna Gáspár-Rády. *Arch. Ind. Hyg.* 17, 227-34 (1947).-- Expts. on 60 cats of both sexes proved that ligation of the anterior descending branch of the coronary artery causes a well pronounced hyperglycemia. The cats were anesthetized with ether with artificial respiration. The rise of blood sugar level began in the 40th min., reached its max. value in the 2nd hr., and remained there even 6 hrs. after the application of the ligature. The hyperglycemia caused by coronary occlusion is absent if the branches of the stellate ganglia and of the vagi leading to the heart are cut previous to the ligature application. No correlation could be found between blood pressure and blood sugar level under such conditions. Ether anaesthesia had no effect on the blood sugar level. 20 references. István Finály

The effect of different ethers on the blood-sugar level. Margit Beznák and István Hajdu. *Arch. Biol. Hung.* 18, 183-8(1948).—Three kinds of ethers: (a) Swedish ether *ad narcosim*, (b) ether sulfuricus serving as basic material for the manuf. of ether for narcotic purposes, and (c) simple com. ether were tested on 71 cats of both sexes of 2.5 kg. av. wt. Anesthesia lasted for 7 hrs. Only (a) caused a marked hyperglycemia. Unpurified ethers caused no hyperglycemia or only a late rise in blood sugar. (b) and (c) were tested for peroxide, aldehyde, and vinyl alc. contaminants. The mortality and other characteristic curves of pure and impure ethers were identical. Seasonal changes caused no changes in the hyperglycemia. The mortality was detd. on rats. István Finály

1177

The effect of different narcotics and coronary occlusion on the blood sugar level. Margit Bezzak. *Arch. Biol. Hung.* 18, 159-161 (1948). Out of 43 cats of both sexes with an av. wt. of 2.2 kg. 14 were anesthetized by chloralose, 9 by pernocton, 15 by avertin, and 5 by ether. Chloralose anesthesia caused hypoglycemia and pernocton a rather irregular increase in the blood sugar. Avertin showed no such effects. Coronary ligation was not followed by hyperglycemia in chloralose, pernocton, and avertin anesthesia. With chloralose the same hypoglycemia was observed as without coronary occlusion. Coronary ligation was followed by hyperglycemia if the cats were anesthetized by crude ether which when applied alone had no effect on the blood sugar. István Bányó

Abstract : Cultures of *Microsporum ferrugineum* were continuously propagated on a medium with filtrates of a culture of *M. lanosum* and at various periods were seeded on Sabouraud's medium. As a result, one stable variant similar in its microscopic picture to *M. lanosum*, and two unstable variants were obtained. In prolonged cultivation of the violet trichophyton on media with decomposition
