Uspekhi Vosstanovitel'noy Khirurgii (Advances in Plastic Surgery), by Prof N. N. Blokhin, Corresponding Member, Academy of Medical Sciences USSR, Series III, No 11, "Znaniye," Moscow, 1955, 23 pp

This booklet describes operations connected with grafting of tissues and organs, including various types of grafts of skin, bone, cartilage, tendons, muscles, and blood vessels. Operations are performed on the face, nose, lips, eyelids, and internal organs such as the scapula and the elbow joint.

Sketches show the area from which grafts were taken. Pictures of the patients before and after the operations illustrate satisfactory results.

"Carbohydrate Function of the Liver During Development of Radiation Sickness," by Prof N. N. Blokhin, I. S. Lukanova, and L. S. Rotfel'd, Leningrad Order of Red Banner of Labor Scientific Research Institute of Blood Transfusion, Meditinskaya Radiobiologiya, Vol 1, No 6, Nov/Dec 56, pp 40-46

Changes in the carbohydrate function of the liver and muscles of dogs were studied at various periods following X-irradiation by doses ranging from 250 to 600 r.

In practically all phases of radiation sickness, regardless of dose, disturbances occur in both the glycogen-forming and the glycogen-fixing functions of the liver. This is confirmed by the adrenalin test, and the test using sugar ingestion, sodium lactate, and insulin.

The pseudodiabetic character of the curve on sugar ingestion and the disturbances in sugar utilization by the muscles lead to the assumption that the insulin-forming functions of the pancreas are disturbed. The administration of insulin on damage by radiation sickness leads to normalization of the above disturbances, thus confirming the accuracy of the assumptions.

The injection of insulin combined with glucose is desirable in the therapy of radiation sickness as it corrects the disturbances in the carbohydrate function of the liver. (U)

Title : Carbohydrate Function of the Liver in Development of Radiation Sickness.
Orig Pub : Dokl. AN SSSR, 1956, 111, No 3, 723-726

Abstract : The dogs were subjected to irradiation with a dose of 250-350 r. Expressed changes of carbohydrate metabolism (CM) in loading with glucose (I) were not discovered; however, in loading with Na lactate (II), some signs of its disturbance were noted. More serious symptoms of CM were observed in dogs irradiated with a dose of 400-500 r. The test with loading with II induced

after 30 min an increase of content of lactic acid (III) in blood by 200%; normalization of metabolism III took place by the 50th days after irradiation. Serious form of radiation sickness developed in dogs at a dose of 525-600 r. Aside from acute anemia (with leucopenia to 500-100 cells in 1 mm³), increase in the blood of sugar and III content was noted. A test with loading with I gave a glycemic curve of diabetic type. A sharply-distrubed type of reaction was observed in loading with II. Injection of 1 ml of 1% solution of adrenalin gave a curve with small and prolonged increase of blood sugar level. For normalization of glycogenic function of the liver, connected with insufficient incretory function of pancreas, insulin was applied in radiation sickness of dogs. Its systematic introduction with large doses of I led to considerable normalization of CM. -- L.M.

TITLE:

The Character of Practical Training Has Changed (Izmenilsya
kharakter praktikuma)

PERIODICAL:

Vestnik Vysshey Shkoly, 1958, # 2, pp 60-61 (USSR)

ABSTRACT:

The article contains particulars on some changes introduced in the students practical training at the Medical Institute of Kalinin. Organic and biological chemistry are the leading general subjects at medical vuzes. The existing system of conducting practical training in organic chemistry (at the 1st course) and biological chemistry (2nd course) had to be revised both from a methodological and methodical point of view. The chair developed 3 exercises in organic synthesis which contained all the basic elements of chemical research. The solution of each of the problems requires 7-8 hours of continuous laboratory work.

The course in biological chemistry was reduced from 82 to 58 hours. Instead of 2 and 4-hour lessons, 6 and 8-hour lessons were introduced. Students of the 3rd semester determine the content of general and residual nitrogen by the Kjeldahl method, gastric juice with qualitative reactions, the properties and quantity of ferment present, etc. In the

Card 1/2

The Character of Practical Training Has Changed

4th semester the presence of sugar in a dog's blood is studied both in a normal state and after introducing glucose, insulin or adrenaline.

The solution of practical problems was taken up in the examination tickets as a separate 4th question, and this increased the students' responsibility in practical training.

TITLE: Small-size atomic electric power installation TES-3

SOURCE: Atomanaya energetika, v. 17, no. 6, 1984, 448-452

TOPIC TAGS: small atomic power installation, portable atomic power installation, nuclear reactor, electric power generation/TES-3 reactor

ABSTRACT: The paper is a summary of the SSSR report #310 at the Third International Conference on Peaceful Uses of Atomic Energy in Geneva, 1964. It describes a movable small-size atomic electric power installation with the water cooled and moderated TES-3 reactor (under 10,000 kw). It consists of four

Card 1/2

L 21211-55

ACCESSION NR: AP5001268

blocks each of which was assembled at the manufacturing plant, and which are placed on four self-propelled flatcars on caterpillar tracks. No housing is required for the installation; the only local preparation needed is the radiation protection. The results with a demonstration model show a satisfactory agreement between the theoretically expected and actually obtained parameters of the installation. Orig. art. has: 4 figures

by reducing the respective very pure oxides with B or boron carbide, were found to contain only the hexaboride phase. The absorption spectra of metals in oxides and hexaborides were obtained with the aid of a focusing tube spectrographs in the second order of reflection from the plane (1011) of a bent quartz crystal. A very strong resemblance was found to exist for the L_{II} and L_{III} absorption edges between the oxides and the hexaborides in the case of Ba and La, and there even exists an analogy between Ba and La. On the contrary, the curves for CeO₂ differ strongly from those for CeB₆, and from the curves for Ba and La compounds. The fine structure of the L absorption spectra of Ba, La and Ce in oxide and hexaborides can be interpreted quite satisfactorily as a result of superposition of continuous absorption and of a group of selective lines which arise mainly due to the transition of the 2p-electrons of metals on the d-symmetry energy levels. There are 8 figures. The most important English-language references read as follows: B. Post, D. Moskowitz, F. Glaser, J. Amer. chem. Soc., 81, 1800, 1956; H. Longuet-Higgins, M. Roberts, Proc. Roy. B103/B110**AUTHORS:** Vaynshteyn, E. Ye., Blokhin, S. M., and Kripyakevich, P. I.**TITLE:** X-ray spectroscopic study of titanium beryllides with a high beryllium content**PERIODICAL:** Akademiya nauk SSSR. Doklady, v. 142, no. 1, 1962, 85-87

TEXT: Following Ref. 1 (E. Ye. Vaynshteyn et al., DAN, 135, 642 (1960)), the authors investigated: (a) Phases of the system Ti-Be with a still higher Be content (alloys containing 88, 90, and 93 atom% of Be). (b) The data of Ref. 1 were checked and defined by increased resolving power of the spectroscopic equipment (APC (DRS) vacuum longwave spectrograph produced at the experimental workshops of the Rostovskiy gosudarstvennyy universitet (Rostov State University)). Alloys were produced by Ye. I. Gladyshevskiy in corundum crucibles in the Tamman furnace in an argon atmosphere. Both emission and absorption spectra were taken. The reflecting (1010) surface of a bent quartz crystal was used. The method of inclined planes was applied to magnify resolution up to 10,000 times. Emission spectra were taken with an aluminum anode. A tantalum anode was

Card 1/5

32818
S/020/62/142/001/016/021
B103/B110

X-ray spectroscopic study ...

used for the absorption spectra. The experimental form and the width of the K_{α_1} line on Ge was investigated to examine dispersion of the function of distortion caused by the parameters of the apparatus, and to determine its half-width. It was found that the two first samples of the alloys had the same trigonal structure: $a = 7.40 \text{ \AA}$, $c = 10.84 \text{ \AA}$, and $c/a = 1.465$. This lattice is equal to that of $\text{Th}_2\text{Zn}_{17}$ (space group R $\bar{3}m$, $Z = 3$); hence, it is concluded that $\text{Ti}_2\text{Be}_{17}$ is produced (in accordance with Ref. 4, see below). It is also possible, however, that solid solutions of TiBe_{12} are involved. These two structures, being very similar to each other (as well as TiBe_2), belong to the class of densest packages of unequally large atoms with high coordination numbers. The line broadening is 0.39 ev, i.e., $\sim 28\%$ of the natural half-width of the line. The form of the experimental spectra and the broadening were corrected according to I. Ya. Nikiforov (Izv. AN SSSR, ser. fiz., 21, 1362 (1957)). It was found that the shape and the relative placement of the K absorption edges and of the last emission lines in the titanium spectra of Ti-Be phases with varying Be content were almost

Card 2/5

32818
8/020/62/142/001/016/021
B103, B110

X-ray spectroscopic study ...

identical. The alloys investigated are very similar with respect to atomic interaction, but differ considerably from beryllides with a lower Be content (Figs. 1, 2). This variation is a result of transitions of the K electron into the portion of the hybridized energy band of the alloy close to the 3d energy levels of the main absorption edge. It follows from the spectra investigated: (1) a considerable weakening of the superposition degree of energy bands of valence electrons of the components in Ti_2Be_{17} ; (2) a weakening of the hybridization degree of the wave functions in the range of the 3d4sp band of the transition metal; and (3) a considerable increase in significance of the role of Be interaction. This leads to a noticeable variation of the effective difference of electronegativities between the two alloy components. Its value can be estimated on the basis of X-ray spectrum data by the relation between the difference (Δx) of the electronegativities of the components of a binary compound and the energy distance (ΔE) ($K_{\beta''} - K_{\beta'}$)

in the X-ray spectrum of the transition metal. Since this value is 4.8 ev, the effective electronegativity of Be must differ in the intermetallic compound from that of Ti by approximately 0.6 ev instead of

AUTHOR: Vaynshteyn, E. Ye., Blokhin, S. M., Paderno, Yu. B.

TITLE: X-ray spectral investigation of samarium hexaboride 27

SOURCE: Fizika tverdogo tela, v. 6, no. 10, 1964, 2909-2912 27

TOPIC TAGS: samarium compound, x ray spectrum, absorption spectrum, europium compound, ytterbium compound, fine structure

ABSTRACT: The samarium hexaboride was obtained by a vacuum-thermal method (G. V. Samsonov and Yu. B. Paderno, Boridy* redkzemel'nykh metallov [Borides of Rare Earth Metals], AN UkrSSR, Kiev, 1964).
For comparison and to facilitate the interpretation of the data, x-ray L_{III} absorption spectra were obtained for europium, ytterbium oxide, and hexaboride, using the same experimental conditions. The absorption spectra were obtained with a DRS-3 long-wave x-ray spectrograph in the first order of reflection from the (1340) plane

Card 1/3

L 12445-65
ACCESSION NR: AP4046596

O

of a quartz crystal. The spectra were recorded photographically. The L_{a2} and L_{a3} lines of europium were used as the comparison lines. The structure of the L_{III} absorption edges of samarium in SmB₆ was investigated in the interval from -120 to +400°C. An analysis of the fine structure indicates that the samarium atoms exist in SmB₆ in two different valence states, which are statistically distributed in crystallographically equivalent positions of the lattice of the compound. The absorption spectrum of samarium in SmB₆ has several features distinguishing it from hexaborides of other rare-earth metals. Chief among these features is the presence of an additional absorption band whose maximum is shifted by about 7 eV towards the longer wavelengths compared with the principal maximum. This hypothesis is confirmed by plotting the theoretical absorption curves corresponding to the different relative contents of the divalent and trivalent samarium and a corresponding analysis. It is estimated that the divalent samarium may amount to $\sim(35 \pm 5)\%$ of the total number of samarium atoms. Orig. art. has: 3 figures.

TITLE: Fine structure of the main x-ray L _{III} absorption spectra and final L ₃₅ emission line of ytterbium in the oxide and hexaboride		
SOURCE: AN SSSR - Doklady*, v. 158, no. 3, 1964, 694-696		
TOPIC TAGS: ytterbium oxide, ytterbium hexaboride, fine structure, absorption spectrum, emission spectrum, valency bond strength, forbidden zone		
ABSTRACT: The fine structure of the emission and absorption spectra of ytterbium oxide and hexaboride were used to study the energy structure of the ytterbium valency bond. The energy spectra of the two compounds differed. In going from the oxide to the hexaboride there was a significant shift in the long wave value both in the maximum of the absorption spectrum (by 4 ev) and in the position of the maximum of the last emission indicating a change in valency from 3 in the oxide to 2 in the hexaboride. In both		

L 31362-65

ACCESSION NR: AP4048384

compounds, the asymmetry index of the emission line approximated unity. In the oxide, the valency band was split, giving rise to a shoulder at 4.2 ev from the main maximum. The fine structure in the oxide was straighter and had 1 maximum, while in the hexaboride there were 3 maxima. The absorption and emission spectra of ytterbium in the hexaboride were very similar due to their greater mutual overlapping resulting in the presence of a weak absorption maximum from the long wave side of the emission band. The absorption complexity of the filling and the peculiarity of the principle of the filling of the wave functions of free electrons forming the valency band is typical of some of the rare earth and other elements with closed outer shells. The width of the forbidden zone E was determined by measuring the energy gap between the short wave edge of the emission and the start of the absorption of the rare earth element in the compounds, which in this case coincided with the inflection point of the absorption curve at half the height of the main maximum: E for the oxide was about 1 ev, and in the hexaboride it was near 0 and never exceeded 0.1 ev. TITLE: X-ray spectral investigation of the valency state of rare earth element
atoms in the hexaborides

SOURCE: Journal neorganicheskoy khimii, v. 10, no. 1, 1965, 121-126

TOPIC TAGS: rare earth hexaboride, rare earth element valence, valence de-
termination, x-ray absorption spectrum

ABSTRACT: The X-ray L-absorption spectra of the rare earth element hexa-
borides and oxides were compared to determine the valency state of the rare earth
element in the hexaborides. The L_{III} absorption spectra of the Ce, Nd, Pr and
Gd oxides and hexaborides were analogous, with coinciding long wave absorption
line maxima, indicating the hexaborides were trivalent, as were the oxides.
Differences in the short wave maxima were ascribed to differences in the crystal
structure of the oxides and hexaborides. In the case of Eu and Yb, the shift of
the absorption edge toward the long wave by the hexaborides in comparison to the

oxides indicated the valency was less than 3. The spectra of Sm in SmB₆ were interpreted to indicate the presence of 35-40% divalent Sm distributed among the trivalent Sm. The effect of temperature (-100 to +600C) on the role of divalent Sm is being studied. Orig. art. has: 9 figures and 1 table.

TITLE:	Analysis of the X-ray L-spectra of rare earth elements		
SOURCE:	Fizika metallov i metallovedeniye, v. 19, no. 2, 1965, 371-374		
TOPIC TAGS:	x ray analysis, absorption spectrum, shift, L band, rare earth element, valence		
ABSTRACT:	Data from X-ray analysis of the L-spectra of rare earth elements are studied. It is found that the increase in the valency of rare earth elements in compounds caused by an additional number of electrons of an atom being drawn into the chemical bond reduces its outer $3d$, $4p$, $5p$ and inner $4f$, $5d$, $6s$ energy levels. Calculation of the shifts shows that this reduction is greater in the case of the inner levels. As the effective charge on a rare earth metal atom in the compound increases, there is a shortwave shift in the L_{III} absorption edge and the last L_{8s} emission band. The increase in the valency of rare earth elements, where the $6s$		
Card 1/2			

L 53686-65

ACCESSION NR: AP5008782

and 5d electrons are the valence electrons is caused by the transition of a 4f electron to a 5d state. The 4f electrons do not take part in the chemical bond. Ionization of the 4f electrons causes a greater shift of levels in atoms of rare earth elements than the ionization of 5d or 6s electrons. This is explained by the greater shift in the L_{III} absorption edge and the $L8_5$ emission line with an increase in valency of a rare earth element that the change in the nature of the chemical bond in compounds with an unchanged valency in the metal atoms. TITLE: X-ray spectral investigation of the valent state of samarium
in the metal and in the monosulfide

SOURCE: Fizika tverdogo tela, v. 7, no. 12, 1965, 3558-3561

TOPIC TAGS: samarium, samarium compound, x ray absorption spectrum,
rare earth element, conduction band

ABSTRACT: In connection with the peculiarities of the electronic
structure of the samarium atom, the authors experimentally investigated
the x-ray L_{III} absorption spectrum of this element in the metal and in
the monosulfide. A thin metallic samarium layer⁶ approximately 10 μ
thick was deposited on an aluminum foil⁶ in vacuum; this deposit was
then sputtered with aluminum in vacuum. An absorber prepared in this
manner was stable in air and had the proper surface density. The L_{III}
absorption edge was obtained with a spectrometer (URS-II) with a quartz

Card 1/2

L 13114-66

ACC NR: AP6000853

crystal bent in the (1340) plane at a radius of 1,000 mm. The results show that in both substances the rare-earth element atoms are present simultaneously in the divalent and in the trivalent states. In the monosulfide, the concentration of the trivalent ions increases with increasing temperature, and this increase is attributed, in accordance with various published data, to thermal excitation of the 4f electrons in the conduction band. Authors thank V. P. Zhuze and his co-workers for interest in the work and for supplying the samarium monosulfide. Orig. art. has: 3 figures.

TITLE: Certain band-structure features of solids in x-ray spectra

SOURCE: Fizika tverdogo tela, v. 8, no. 8, 1966, 2420-2426

TOPIC TAGS: x ray spectrum, alkali halide, spectral fine structure, titanium oxide, absorption coefficient, K band, L band

ABSTRACT: The relationship between the positions of the extremal points of the band structure and fine structure of x-ray absorption by atoms in solids is studied. To determine to what degree general ideas agree with the theory, a study is made of the fine structure of the K and L atomic spectra of alkali halide crystals, namely the K and L absorption edges of potassium and chlorine in KCl. The characteristic points of the resulting curves are discussed and related to specific transitions. The maxima and minima of potassium and chlorine are interpreted. A comparison is made in a table of the fluctuation of the absorption coefficient in the K and L spectra of chlorine and potassium with the characteristic points of the band structure of KCl. Satisfactory
