ABSTRACT: A casting department, designed by the MNIPTMASH institute for producing 1000 tons/year, is described. The project includes three independent sections: a section for producing low temperature melting patterns, application of heat resistant layers, drying of the molds and burning out the patterns; a section for drying, forming, firing, pouring, and removal of the castings; a section for trimming, cleaning, and leaching of the castings. Yearly output per worker will be 1.5 times higher than at the casting department of the Podol'sk mechanical factory and 2.5 times higher than at the existing casting department of the Kuznetsk factory. 4 illustrations. C:111/C444

Convergence of the discrepancy . . .

for  $n \rightarrow \infty$ ,  $u_n$  being approximations of the solution of (1), obtained by the Bubnov-Galerkin method with  $\{\varphi_n\}$  as coordinate elements.

If in (1)  $K = 0$ , then it follows that the discrepancy  $Au_n - f$  of the Ritz method for  $Au = f$ ,  $A$  being a positive definite self-adjoint operator and  $u_n$  being approximations according to Ritz, also converges to zero, if  $\{\varphi_n\}$  is the used coordinate system.

In the separable Hilbert-space  $H$  one considers

$$Lu \equiv Au + Ku = f \tag{5}$$

where  $D(A)$  is dense in  $H$ ,  $D(A) \subset D(K)$ . Let  $\{\lambda_n\}$  be a sequence of positive numbers  $\{\varphi_n\}$  be complete and orthonormal in  $H$ , and let

$$A\varphi_n = \lambda_n \varphi_n + \psi_n .$$

Let  $A^{-1}$  exist; the operators  $KA^{-1}$  and  $T_1 v = \sum_{k=1}^{\infty} (v, \varphi_k) \frac{\psi_k}{\lambda_k}$  be

Card 3/4

30691

S/020/61/147/002/001/027  
C111/C444

Convergence of the discrepancy . . .

completely continuous in H. Let (5) possess a unique solution. The approximate solutions of (5) are determined by the set-up

$$u_n = \sum_{k=1}^n a_k \varphi_k, \quad a_k \text{ being found out of}$$

$$(Lu_n, \varphi_m) = (f, \varphi_m), \quad m = 1, 2, \dots, n \quad (6).$$

It is shown that (6) uniquely is solvable for sufficiently large n, and that  $\|Lu_n - f\| \rightarrow 0$  for  $n \rightarrow \infty$ .

There are 3 Soviet-bloc and 1 non-Soviet-bloc references.

TITLE : The Influence of Soil Conditions on the Productivity of Oak Forests of the Voronezh Reservation  
ORIG. PUB. : Tr. Voronezhsk. gos. zapovednika, 1957, vyp. 7, 73-81  
ABSTRACT : An analysis of the chemical composition of soils under oak forests of varying productivity showed that an increase in quality class was caused by an increase in soil content of accessible N compounds, ash elements, and by an improvement in the water-air cycle. The productivity of stands is increased, in particular, on soils having loamy layers. With an improvement of site conditions, the organic volume of the trees increases and the root systems are more pronouncedly branched and deepened. The productivity of oak also increases in stands containing ash, linden and sharp-leaved maple as associates. Oak forests of all site classes show a positive effect on the soil-forming

TITLE: The application of the electronic digital computer "Strela" to some  
astrometric problems

PERIODICAL: Referativnyy zhurnal, *Astronomiya i Geodeziya*, no. 4, 1961, 19, ab-  
stract 4A225 ("Tr. 14-y Astrometr. konferentsii SSSR, 1958", Moscow-  
Leningrad, AN SSSR, 1960, 182 - 185; French summary)

TEXT: This is a report on application of a "Strela" electronic digital com-  
puter to solving the following astrometric problems: determination of positions  
of minor planets, calculation of stellar proper motions, processing of meteoric  
photographs (see RZhAstr, 1959, no. 10, 8254), and obtaining photographic positions  
of Earth's artificial satellites (see RZhAstr, 1960, no. 9, 9147). Calculation  
schemes are given for the first two problems. It takes 21 min to calculate a posi-  
tion of a minor planet (20 hours for manual calculations); the computer can yield  
proper motion of 114 stars in one procedure.

TITLE:

Synthesis of Coproporphyrin by the Yeasts *Candida Guilliermondii* (Sintez koproporfirina drozhzhami *Candida guilliermondii*)

PERIODICAL:

Doklady Akademii nauk SSSR, 1958, Vol 123, Nr 6, pp 1077 - 1080 (USSR)

ABSTRACT:

The porphyrins, either in combination with metals (iron or manganese) or free, take part in highly important redox reactions of the cells: photosynthesis and respiration. Free porphyrins were found in bacteria, mold fungi and yeast fungi (Refs 1,8). It is mostly coproporphyrin that can be accumulated both in the cells and in the culture medium. The formation of higher amounts of coproporphyrin usually occurs as a consequence of a disturbed synthesis of hematine or of bacteriochlorophyll or as a consequence of an iron deficiency in the culture medium (bacteria) (Ref 7). In yeasts, the insufficient supply of riboflavine to the cells (Ref 10) is said to be the cause of it. The authors prove in their paper that some

Card 1/3

Synthesis of Coproporphyrin by the Yeasts *Candida*  
*Guilliermondii*

SOV/20-123-6-33/50

yeast fungi accumulate coproporphyrin in spite of an intense riboflavine synthesis. Thus some other causes for the porphyrin formation than riboflavine deficiency may exist. The yeast species mentioned in the title (ATCC 9058) was cultivated on a sugar-mineral culture medium of Berkgol'der which glycocoll and a sufficient iron quantity. In addition to the disappearance of the cytochromes from the cells a substance which was red fluorescent in ultraviolet rays was accumulated which was determined as coproporphyrin (Refs 6,8). The elimination of glycocoll from the culture medium (Table 1) as well as certain other culture media led to a decrease or even to a stop in the coproporphyrin formation. A subspecies of this yeast species, *C. guilliermondii* var. *membranaefaciens*, further *Saccharomyces ellipsoideus* 465 did not form considerable coproporphyrin amounts under similar conditions (Fig 2). It becomes more and more convincing that the same low-molecular weight precursors, e.g. glycocoll (Refs 7,9), take part in the formation of the prophyrins, of the riboflavine and of vitamin B<sub>12</sub> in certain stages of the synthesis. The pheno-

SOV/20-123-6-33/50

menon of "porphyria" in microbe-"hypersynthesizers" of these vitamins points, according to the authors' opinion, to an increased lability of the metabolism which is connected with the formation of heterocyclic compounds. *C. guilliermondii* synthesizes considerable quantities of the III isomer of the coproporphyrin. It is accumulated in the vacuole apparatus of the cells. The yeast autolysate stimulates the formation of coproporphyrin. There are 2 tables and 12 references, 1 of which is Soviet.

ABSTRACT: Results are presented from investigations performed using a network mock-up to synthetically test high-voltage circuit breakers and dischargers to be used in 500-1250 kv power networks. The testing of individual spark-damping elements of breakers is statistically justified. A circuit for combined testing of valve dischargers, including a power system which serves as a source of accompanying current, is analyzed. This system provides full correspondence in current and voltage levels, capacitance and inductance to an actual power network, allowing the breakers to be tested with assurance that the test will correspond to actual operating conditions of the breakers after they are installed in power systems. TITLE: The Hydrogen Permeability of Liquid Basic Slags  
(Vodorodpronitsayemost' zhidkikh osnovnykh shlakov)

PERIODICAL: Nauchnyye doklady vysshey shkoly. Metallurgiya, 1958,  
Nr 1, pp 31-36 (USSR)

ABSTRACT: In the present paper the results of investigations on the hydrogen permeability in slags, in relation to their chemical composition are given. The hydrogen permeability of the slags is influenced by the chemical composition of the slags and by their physical properties. The chemical composition of the slags investigated was divided into 4 groups, and the basicity of the slags was represented by the ratio  $\frac{\text{CaO}}{\text{SiO}_2}$ . The basicity of the first group of slags varies between 0,87 - 3,40, the basicity of the second group from 2,12 - 2,20, the basicity of the third group from 2,20 - 2,25 and that of the fourth group from 2,20 - 2,25.

Card 1/3

It was found that the hydrogen permeability of the slags

## The Hydrogen Permeability of Liquid Basic Slags

SOV/163-58-1-7/53

depends on the content of MnO, FeO and MgO. This dependence was also graphically shown.

The viscosity of the slags increases abruptly according to their increase in basicity.

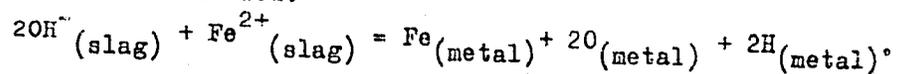

The process of the transition of hydrogen through the layer of the liquid slag is divided into three stages:

- 1) The transition of the hydrogen from the gas phase to the slag after the reaction:

- 2) The diffusion of the hydroxyl ion through the layer of the slag metal.

- 3) The transition of the hydrogen from the slag in the metal after the reaction:

When the content of FeO, MnO and MgO is increased in the slag the binding energy of  $\text{O}^{2-}$  in the molten slag increases, which decreases the activity; in consequence of this the first stage takes place more slowly. The higher content of FeO in the slag decreases the activity of  $\text{O}^{2-}$  and the hydrogen

Card 2/3

The Hydrogen Permeability of Liquid Basic Slags

SOV/163-58-1-7/53

permeability of the slag to a greater extent than MnO. When the MgO content in the slag is increased the viscosity of the slag is increased. An increase in the MgO content of the slag causes a very sharp decrease in the hydrogen permeability of the slag. There are 3 figures, 2 tables, and 4 references, 4 of which are Soviet.

TITLE: The Use of Silicochrome When Smelting Steel in Open Hearth Furnaces

PERIODICAL: Stal', 1960, No. 7, pp. 607 - 608

TEXT: In the Chelyabinskiy metallurgicheskiy zavod (Chelyabinsk Metallurgical Plant) and in the Zlatoustovskiy metallurgicheskiy zavod (Zlatoustovsk Metallurgical Plant) in melting low-carbon chrome steels: 18XГТ (18 KhGT), 17XH2 (17KhN2), 20XH (20KhN), 12 - 20XH3A (12-20Kh2N3A), 12-20X2H4A (12-20Kh2N4A) and medium carbon chrome-containing steels: 35-45XH (35-45KhN), 33-37XC (33-37KhS), 30-35XГСА (30-35KhGSA), 30XГТ (30KhGT) five types of silicochrome were applied having the following Cr, Si and C content (in %):

Silicochrome	12 - 20	40 - 50
--------------	---------	---------

Card 1/3

S/133/60/000/007/004/016

The Use of Silicochrome When Smelting Steel in Open Hearth Furnaces

Cr	49 - 56	29 - 39
Si	15 - 19	40 - 54
C	2.75 - 4.50	0.12 - 0.20

When using 12 - 20 type silicochrome 7 - 20 kg/t were added, whereas of the 40 - 50 type silicochrome about 4.5 kg/t (in the ChMZ) and about 2.3 kg/t (in the ZMZ) and for 30 - 35 KhGSA 6.5 kg/t were added. When applying silicochrome, steels of the required composition could be produced without any difficulty and the duration of the preliminary deoxidation could be reduced by 5 - 9 min in both plants, (i.e., by 0.3 - 1.5% of the melting time). The amount of chrome, manganese and silicon scale is practically the same as for the conventional method (in Zlatoustovsk: Cr 18%, Mn 20%, Si 32%, in Chelyabinsk: Cr 19%, Mn 25%, Si 38%). The lower amount of chrome scale in the ZMZ can be explained by the higher residual chrome content of the metal before deoxidation: 0.13 - 0.31% as compared to the values obtained in the ChMZ : 0.06 - 0.13%. In order to obtain an optimum economical effect, when melting medium-carbon-chrome steel, the amount of 20 type silicochrome should be 11 - 13 kg/t in the ChMZ and 8.5 - 9.5 kg/t in the ZMZ and the silicon used in conventional melting be replaced by blast-furnace ferrosilicon. When

Card 2/3

S/133/60/000/007/004/016

The Use of Silicochrome When Smelting Steel in Open Hearth Furnaces

melting low-carbon steels, 12 - 13 kg silicochrome per ton should be used when the chrome content of the steel is below 0.9% and 15 - 17 kg of silicochrome per ton when it is above 0.9%. The use of silicochrome of the 40 and 50 types is economical only in the melting process of low-carbon steels. The holding time of the bath after adding 20 type silicochrome, when melting steels of a chrome content below 0.9% is only 15 - 20 min and for steels with a chrome content above 0.9% it is 20 - 30 min, on account of the decrease in weight of cold additives in the furnace (15 - 20 kg/t) and a more rapid absorption of silicochrome as compared to ferrochrome. The initial cost of steel when using silicochrome in the melting process was decreased in both plants by a total of 2 - 2.5 million roubles per annum, from 2 roubles/ton for the 40Kh type steel to 20.4 roubles/ton for the 20Kh type steel in Chelyabinsk and from 1.1 rouble/ton for the 30KhSA type steel up to 12.6 roubles/ton for 20Kh steel in Zlatoustovsk. There is 1 table. ✓

**PURPOSE:** This collection of articles is intended for engineers and technicians of metallurgical and machine-building plants, senior students of schools of higher education, staff members of design bureaus and planning institutes, and scientific research workers.

**COVERAGE:** The collection contains reports presented at the fifth annual convention devoted to the review of the physicochemical bases of the steelmaking process. These reports deal with problems of the mechanism and kinetics of reactions taking place in the molten metal in steelmaking furnaces. The following are also discussed: problems involved in the production of alloyed steel, the structure of the ingot, the mechanism of solidification, and the converter steelmaking process. The articles contain conclusions drawn from the results of experimental studies, and are accompanied by references of which most are Soviet.

TITLE:1 News in brief

PERIODICAL: Stal',<sup>21</sup> no. 6, 1961, 518

TEXT: In the Chelyabinskiy nauchno-issledovatel'skiy institut metallurgii (Chelyabinsk Scientific Research Institute of Metallurgy) in cooperation with the Chelyabinskiy metallurgicheskiy zavod (Chelyabinsk Metallurgical Plant) the application of oxygen and a steam-oxygen mixture in the open-hearth furnace process was investigated. The silicon content of the pig-iron could be removed in a mixer with a capacity of 1,300 tons and having a fireclay vault by means of a steam-oxygen mixture. No brown smoke developed during the process. When the mixture was blown through 40 tons of pig-iron with an initial silicon content of 0.96% and a manganese content of 0.86% for 4 hours and 30 minutes, 0.34% silicon and 0.23% manganese were burnt out. The oxygen consumption increased from 500 to 1,900 m<sup>3</sup>/hour, steam consumption from 550 to 1,300 kg/hour. The water-cooled single-jet tuyères were immersed in the pig-iron to a depth of 200 - 300 mm. The duration of numerous experimental smeltings in a 370-ton

Card 1/2

furnace, blowing 1,000 - 1,200 m<sup>3</sup>/hour of industrial oxygen into the bath by both tuyères, was 40 - 60 minutes shorter than the usual smelting time. Oxygen-blowing was started when the last ladle of pig-iron was poured and lasted until the end of smelting. The specific fuel consumption decreased by 6%. ✓
