

RC

Theory of interaction of particles carrying double electrical layers, and the aggregative stability of hydrophobic colloids and disperse systems. B. Dzuganov (Bull. Acad. Sci. U.R.S.S., Ser. Chim., 1937, 1159-1164).—Theoretical. Formulae, based on the Gouy-Debye-Hückel theory of diffuse ionic layers, are derived, from which the rate of coagulation of colloids may be calc. as a function of the ζ -potential, the radius of the particles, and the thickness of the ionic layer. Systems containing particles of a radius of the order of 10^{-4} cm. are stable when the ζ -potential > 30 mv. R. T.

* 1226. Ultra-Short Illumination of the Eye. B. Derjugin. *Comptes Rendus (Doklady) de l'Acad. des Sciences, U.S.S.R.* 17, 8, pp. 409-410, 1937. In English.—A rotating mirror device is described for the investigation of the effect of single light stimuli (duration $10^{-8} - 10^{-7}$ sec.) on the eye. An advantage of the apparatus described is that the illuminated area of the retina is fixed, and not changed by the use of the rotating mirror. The interval between successive flashes is also variable over a considerable range. A. H.

DERYAGIN, B. V.

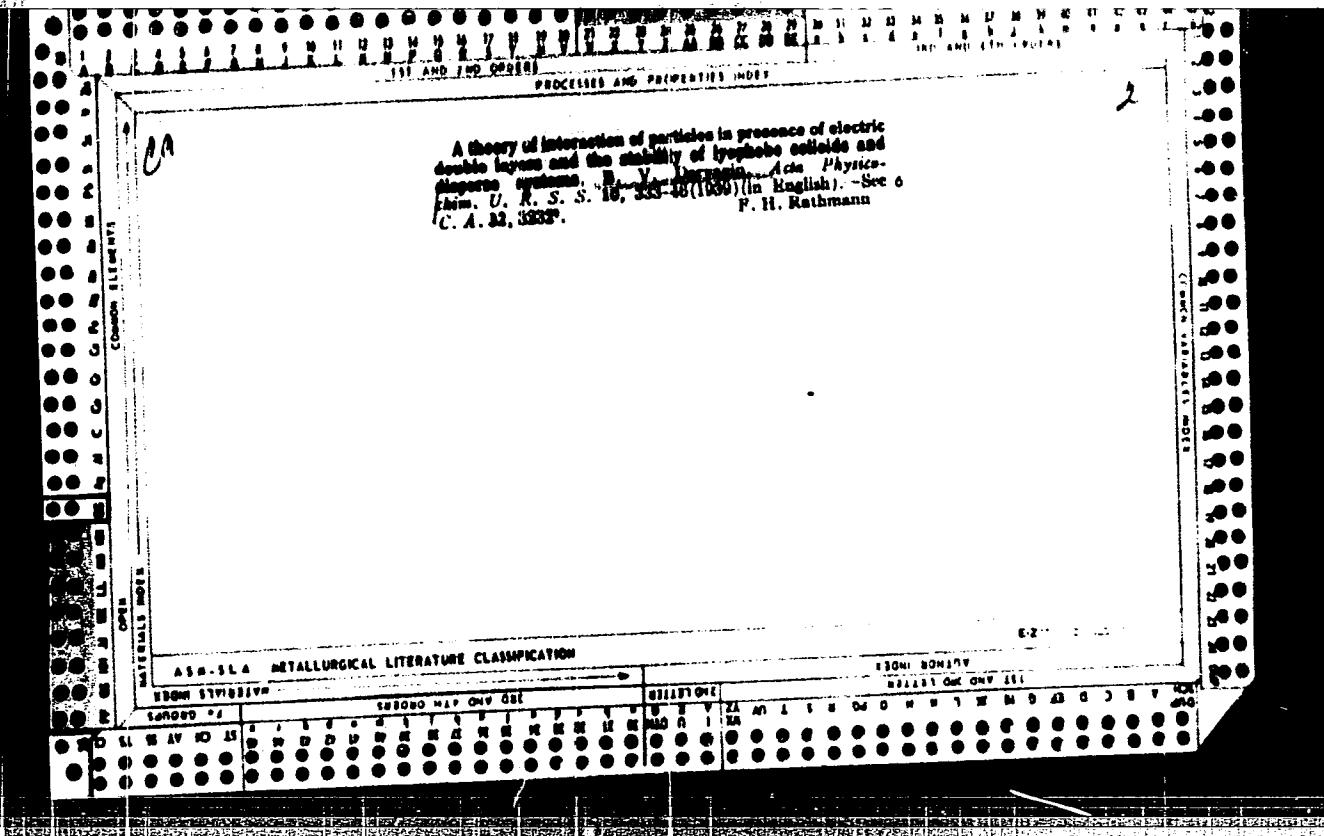

Theory of nondissolving volume (i. e., of the negative adsorption). *B. Deryagin, Colloid J. (U. S. S. R.) 5, 227-61 (1939).* ---A relation between the nondissolving vol. ϵ and the potential of adsorption forces is deduced and discussed.
J. I. Bikerman

Theory of nondissolving volume. II. B. V. Deryagin. *Colloid J. (U. S. S. R.) 6, 607-11 (1939); cf. C. A. 33, 5490.* ---With Birkhoff's theory of the structure of surface layers and the Gibbs adsorption theorem as a basis a relation is derived between the "nondissolving" vol. and the concn. of the substance the neg. adsorption of which is measured. The consts. used for checking the theory give a curve of a predicted shape but an impossible value for the const. involved (vol. of the solute in the soln.).
J. J. Bikerman

Anomalous properties of thin multimolecular films. V. Experimental investigation of multimolecular solvate (swelled) films as applied to the development of a mathematical theory of the stability of colloids. B. DYMACHUK and M. KUMAKOV (Acta Physicochim. U.R.S.S., 1939, 10, 25-44). An improved method of measuring the thickness of films of liquid between a solid surface wetted by them and a gas bubble is described (cf. A., 1937, I, 358; 1938, I, 184). The importance of such films for the conception of solvation and for the theory of colloid stability is discussed. F. L. C.

Lab. of Thin Films, Dept. of Phys. Chem. of Dispersive Systems and Surface Phenomena, the Colloidal-Electrochem. Inst. of the Acad. of Sciences, Moscow.

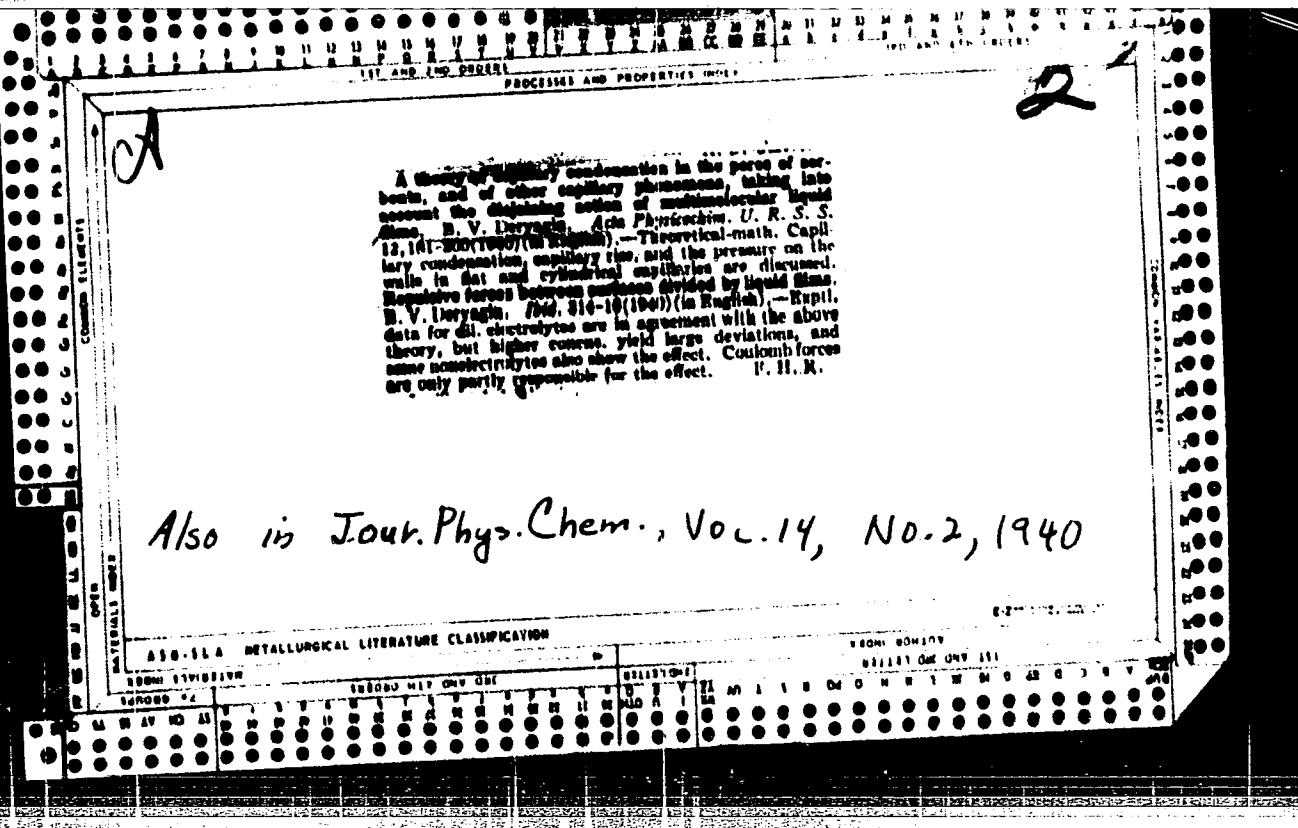

STRUCTURE AND PROPERTIES

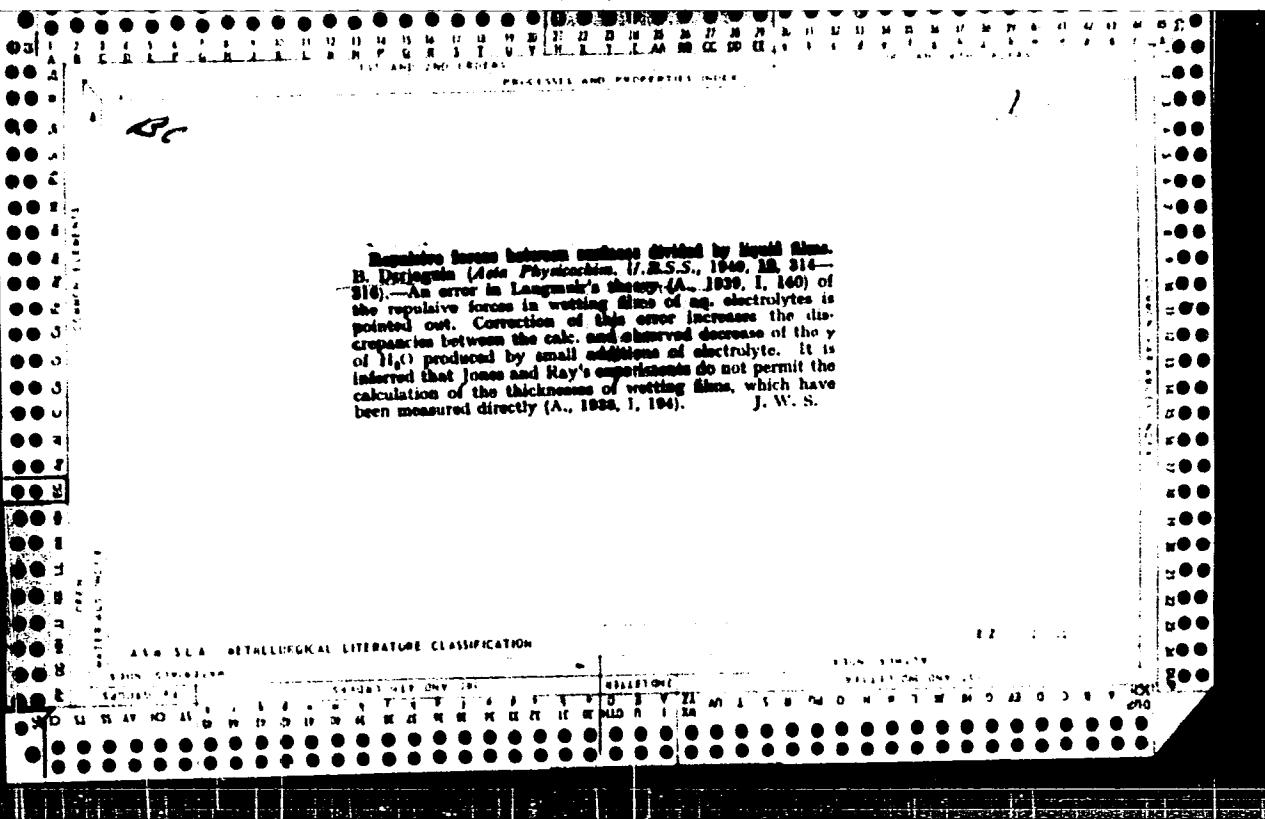

Range of molecular action of surfaces and multilayered solvate (adsorbed) layers. B. V. Deryagin, M. Kusakayev and L. Ledeburka, *Comp. rend. acad. sci. U. R. S. S.*, **33**, 771-8 (1939); cf. *C. A.*, **31**, 6049. — The thickness, h , of a film formed by H_2O between a gas bubble and water is about 1.5×10^{-8} cm. Measured values of h at various values of the excess internal pressure P correspond with states in thermodyn. static equilibrium; this indicates a range of action of mol. surface forces of $2-3 \times 10^{-8}$ cm. For electrophysis, the film collapses when h becomes small, and an upper limit to the thickness of stable wetting layers of liquids on solids exists. Dissolved substances alter the form of the P -curve. The variation of h with solute concn. shows that h of adsorbed layers at soln.-solid interfaces is about 10^{-8} cm. The interpretation of the pressure P in soln. is discussed. B. C. P. A.

Theory of capillary condensation and other capillary phenomena taking into consideration the disjoining effect of multicomponent liquid films. R. Bergman (*J. Phys. Chem.*, 1940, **44**, 137-147) - Because of the disjoining effect of thin films (cf. A., 1940, 1, 141) capillary condensation may cause swelling of the sorbent. This effect is also involved in the capillary rise in slots and cylindrical capillaries.

Measurement of the Viscosity of Wall-adjacent Boundary layers of Liquids by the blow-off method. B. Derygin, G. Strukhovskii, and D. Malyshcheva. *Acta Physicochim. U.R.S.S.*, 19, 641-672 (1944).—The viscosity of liquid layers lying within the range of the surface forces acting on a solid boundary was measured by a method based on the flow of a liquid through a fine (0.17 mm wide) slit between two solid walls (Derygin and Samygin, Report of the Symposium *Friction and Wear in Machines*, Vol. II, p. 271 (1946)). The method permits the determination of the velocity profile and the magnitude of the viscosity in 10^{-6} cm., and thicker boundary layers. Normal liquids and unthickened oils gave an interference pattern with equidistant bands to within 10^{-6} cm. of the interface. Turbine oil and spindle oil thickened with Al naphthalene gave a broadened second interference band, whereas other Al soaps did not. This increase in the viscosity at the interface is interpreted as an intensified or preferential development of a colloidal structure close to the oil-metal interface. The noticeable drop in viscosity at about 0.5μ from the interface is attributed to the impoverishment of the corresponding layers with respect to Al naphthalene, which was consumed in surface gel formation. The ability of Al naphthalene to increase the viscosity in the layer adjacent to the solid surface and leave the bulk viscosity almost unaltered makes possible improvement in the lubricating action of boundary films without changing

the mech. properties of the bulk of the lubricant. More detailed investigations are being made in the region around 10^{-8} cm. from the interface with more precise photometric equipment. Franz Goret

ABSTRACTS OF METALLURGICAL LITERATURE

APPROVED FOR RELEASE: Thursday, July 27, 2000 CIA-RDP86-00513R00031022C

2198. A NEEDLE PROFILOMETER STUDY OF THE OILINESS OF LUBRICANTS.
Derjaguin, B. and Pichagin, E. (Compt. Rend. (Doklady) Acad. Sci. U.S.S.R., 1945, 52, 259-62) The cause of "oiliness" in a lubricant is usually regarded as the formation of a polymeric boundary film on the metal surface. This film in a narrow gap between two surfaces may develop a disjoining pressure which decreases as the width of the interstice grows. To estimate the thickness of this film for kinetic friction, to estimate the pressure when slip developed, these experiments were undertaken. The method consisted in determining by needly profilometer. The method when oiling, and after oiling, to estimate the apparent decrease in roughness. The effect is characterised by $\Delta d/d$. If the oily layer were the same thickness overall then Δ should be zero. It may be expected that at the protuberances the pressure will be greater than at the depressions. It should cause it to pierce the film to a greater depth, which will be counterbalanced by the disjoining effect of the thinner film.

Experimental determination of the thickness of the liquid layer left on a solid wall behind the receding meniscus. D. Beryugin and A. Titovskaya. *Doklady Akad. Nauk S.S.R.* 100, 207-10 (1948); cf. *C.A.* 40, 7744.—If the meniscus moves along the wall at the rate U , the thickness δ of residual layer of liquid left behind on the wall is theoretically related to its surface tension σ , d. ρ , and viscosity η , by $\delta = \sigma^2/\eta\sigma(x)$, where $\sigma = \sqrt{\sigma_0/\rho}(x)$ and $x = (\eta U/\sigma)^{1/2}$ (*D. C.A.* 38, 1801; 40, 7744); for $x = 0$, $\sigma(x) = 0.94\sqrt{\sigma_0}$, and for $x \rightarrow \infty$, $\sigma(x) \rightarrow 1$. If the thickness δ is not uniform, the formulas for the av. thickness $\bar{\delta}$ are, for $x = 0$, $\bar{\delta} = 0.94(\eta U)^{1/2}$; [1 - 0.268((\eta U/\sigma)^{1/2})/\log(\eta U/\sigma)]^{1/2} (I) and for $x \rightarrow \infty$, $\bar{\delta} = 1/\sqrt{\eta U/\sigma}$ (II). Exptl. tests were made with 11 various oils and paints, of rods in oil of different σ , with δ being detd. by weighing a glass cylinder of 3.5 cm. diam., wall thickness 0.18 cm., immersed in the liquid and either raised vertically at the rate U or kept stationary, with the surrounding liquid being displaced off at that rate. The "end effect," i.e. the effect of the liquid adhering to the bottom end of the cylinder, was eliminated by weighing the cylinder once from immersion to a depth of 2 cm., then from 18 cm.; the difference gives the wt. of the liquid layer over a length of 10 cm. If the results are plotted in the form $\log \bar{\delta}$ against $\log x$, the fit formula I up to $x = 1.137$, formula II from that point upwards, deviations never exceeding 5-8%. There is no region in which neither formula is applicable. N. Thom

Measurement of the refractive index of this class of aluminum oxide. R. M. Fridlyand and B. V. Lopatin. *J. Tach. Phys. (U.S.S.R.)* 16, 365-70 (1953).—To compare Al_2O_3 obtained from Al by heating at 550° (I) to that prep'd. by oxidation on the anode of an electrolytic bath (II), as of both types were detd. An indirect method measuring the Brewster's angle was employed, in $n = 1/\rho$, where ρ is the angle of complete polarization (Brewster's angle) (cf. Blodgett, *C.A.* 29, 5328^a and Blodgett and Langmuir, *C.A.* 31, 7700^b). A part of a glass plate was covered with the film under investigation and the plate was illuminated by light polarized in a plane perpendicular to the plane of the incidence of light. When Brewster's angle characteristic for the matter of the film was formed by the incident light and the plate, no light was reflected from the borderline film-air and the plate reflected the light uniformly. The Brewster's angle was then detd. from the position of the plate relative to the reflected beam. The sharpest contrast of intensity after passing the Brewster's angle was attained when the thickness of the film corresponded to the condition of min. interference: $2ds \cos r = \lambda/m/2$ where d is the thickness of the film, $n =$ refractive index, $r =$ the angle of refraction, $\lambda =$ the wave length, and $m =$ an odd whole no. The samples were prep'd. by covering a glass plate with an Al film by the evapn. method in vacuum. The Al was removed from half of the plate with alkali soln. and the Al on the other half was converted into oxide by method I or II. The thickness of Al films was detd. according to data by Walkenstein (cf. *C.A.* 36, 5703^c) and also was evaluated from the amt. of tension necessary to convert the film completely

into the oxide. The av. s for Al_2O_3 of type I was 1.9, compared with 1.00 for type II. Five samples were heated after the first data, for 3 hrs, at 480-500°; the changes in s after that were within exp'l. error. A drawing of app. and tabulated exp'l. data are given. N. Thun

value of //, determined by a slider method, the relation between // and solute concentration having been determined in preliminary experiments with thick films of known solute concentration. From experiments over a range of initial solute concentration and film thickness, adsorption isotherms for stearic, palmitic, myristic, and caproic acids, and octyl and cetyl alcohols, all on steel at 12-15°C, were determined. The relation between the solute concentrations in the absorbed films and the frictional characteristics were determined, and it was concluded that some degree of metal-to-metal contact between the slider and plate persisted until the adsorbed solute layer was completely established.

The cause of the zooluminescence of liquid drops upon contact. B. Deryagin and P. Prokhorov (Acad. sci. U.S.S.R., "Moscow"). *Tezhst. rend. akad. sci. U.R.S.S.* 54, 207-10 (1940).—The thickness and profile of the gap between 2 drops being forced out of 2 capillary tubes by the same hydrostatic head were observed by microscopy and photomicrography of the interference bands resulting from illumination of the gap with monochromatic light. The outer edge of each drop was crescent-shaped. The gap between the drops was thus thickest at the center. Since the profile remains unchanged for long periods of time, an excess pressure, Δp , must exist in the center space. Δp is due to the unbalanced diffusion of the vapor from the center space and, with it, to the outside where its content is low. Δp for $BtOH$ in a chamber whose edges were sept. by a gap of 2.8 μ from a cover plate was 1020 dynes/cm.², great enough to overcome capillary attraction. The atm. around the drops could be controlled. As it contained more of the liquid vapor, sept. of the drops decreased until at satn. the drops coalesced at once. More volatile liquid produced broader gaps between the drops. For hexane, vapor pressure 120 mm., the min. thickness of the gap was 0.8 μ ; for pentane, vapor pressure 420.2 mm., it was 0.78 μ . F. Kinetic phenomena in boundary films of liquids. I.
Capillary osmotic. B. V. Deryagin, G. Sidorenkov, E.
Zubanovskii, and N. N. Krasil'cov. *Kolloid. Zhur.* 9,
353-47 (1947).—A master-glass filter caps. a wide con-
tainer from a glass capillary, both filled with H_2O . When
 $AcNH$, boric acid, lauric acid, or sucrose is
introduced into the container, the molecule in the capillary
starts to move. This movement cannot be accounted for
by hydrostatic pressure. A cylinder is connected by a narrow tube
top with a tank contg. dil. McOll (d. 0.95) and at the
bottom with a tank contg. sucrose in this dil. McOll
(d. 0.97). The boundary between the 2 solns. is originally
situated in the middle height of the cylinder and marked
by wax spheres, d. 0.945. When diffusion proceeds, the
spheres spread over a layer up to 1 cm. thick, and the
smaller the sphere (their radii ranged from 0.01 to 0.13
cm.) the higher it is in this layer. The effects are
attributed to a diffuse adsorption layer of neutral mols. at
solid walls, which layer gives rise to phenomena analogous
to those caused by the diffuse double layer of ions.

PROCESSES AND PROPERTIES INDEX			
<p><i>Note:</i> Determination of the viscosity of multicomponent liquid boundary layers by the blowing-off method. B. V. S.N. 68, 63-6 (1948).—Under the action of an air stream blown parallel to a thin film of liquid spread on a solid surface, the film acquires, after a time τ, a profile characterized by plotting its height h against the distance x from the edge of the solid surface. From data of h, by the "differential" viscosity $\eta(h)$ (D., et al., C.A. 36, 10110) is obtained by $\eta = \dot{\gamma}/d\eta/dx$, where $\dot{\gamma}$ = shearing stress due to the air stream, measured with the aid of a differential manometer, $\dot{\gamma} = \text{rate of flow of the liquid}, d\eta/dx = -dx/dh$. In films of paraffin oil, a nonpolar liquid, on steel, η, even at 10^{-4} cm. from the solid surface, does not differ from the viscosity of the bulk of the liquid. In contrast thereto, polar liquids, tributyrin, a dioleinic hydrocarbon (Cobia), castor oil, show a different η in the layer close to the wall. In the case of tributyrin, η is constant within a thickness h_0 from the wall, then it goes over discontinuously into $\eta = \eta_0$. In the case of Cobia, there are 2 well-delineated layers, one of thickness h_0 in which $\eta > \eta_0$, the other with $\eta < \eta_0$; at the distance h_0 from the wall, this layer goes over discontinuously into $\eta = \eta_0$.</p> <p>A similar situation is found in the case of an American winter aviation oil. Addns. of stearic acid, 0.01, 0.05, and 0.1%, and of oleic acid, 0.1 and 1%, to paraffin oil, give rise to a boundary layer of $h \sim 10^{-4}$ cm. with $\eta > \eta_0$. Addns. of diethyl sebacate, 0.001, 1%, create 2 boundary layers, a deep one with η slightly less than η_0, and an outer one with $\eta < \eta_0$. The behavior of the different liquids is characterized by values of h_0 and $\eta_0 = \eta_0/\eta_1$ or, in the case of presence of 2 layers, by h_0, η_0, and h_1, $\eta_1 = \eta_1/\eta_0$; e.g., paraffin oil + 0.1 and 1% oleic acid, h_0 80 and 68 μ, η_0 1.09 and 1.22; Cobia, h_0 120, η_0 1.13, h_1 100, η_1 0.88; castor oil, 60, 4.03, 200, 0.90; paraffin oil + diethyl sebacate 0.1%, 90, 0.94, 180, 0.88. The latter instance illustrates the effect of orientation in the adsorbed layer, as diethyl sebacate must be lying flat on the steel surface. Orientation must be the drag factor for the change of η in the boundary layer, as these changes cannot be accounted for by changes of concn. N. Thon.</p>

DEP/KAG/JV:

A study of reasons of noncoalescence of liquid droplets under static conditions (under prolonged contact). Deryugin and P. I. Prokhorov. *Nauye Idei v Khimii i Tekhnike Akademii Nauk S.S.R., Inst. Fiz.-Khim., Sbornik Statei 1946, 84-101.*—A method was developed that permits study of the shape and dimensions of the air space between 2 touching half-droplets, while preventing their coalescence. It involves microscopic observation of interference rings with monochromatic light of continuously variable wave length, and permits variation of the compn. of the surrounding atm. The air space has a form resembling a crater inverted over another crater, and the distance between the rims of the opposite craters is the parameter studied. This gap is larger for liquids with higher vapor pressure, and it decreases with increasing concn. of the vapor in the surrounding atm. The non-coalescence of the half-droplets is explained by an excess pressure in the air space caused by the diffusion of the vapor of the substance through the gap between the rims of

the air space, while air is drawn into the air space. A study was made with an app. designed to serve as a model illustrating the diffusion theory, and an equation was derived for this case, relating the value of the excess pressure to the size of the gap and properties of the substance. The exptl. results obtained on this app. closely follow the theoretical values. The equation applied to half-droplets of Et₂O gives a value for the gap several times as large as the exptl. value. This is explained by the flow of the liquid, in the outer layer of the half-drops, from the center of the air space toward the gap between the rims. This effect was absent in the expts. with the model. The diffusion theory explains the dependence of the size of the gap on the vapor pressure of the liquid and on the concn. of the vapor in the surrounding atm.

Peculiarities of behavior of thin layers of polymers of vinyl ethers and their solutions on metallic surfaces. B. V. Deryagin and N. N. Zakhareva. Izdatelstvo v Otdelenii po Radiofizike, Sverdlovsk, Dzhaly, Ural Krai. Vyrobnoye Izd. Sverdlovsk, Akad. Nauk S.S.R. 1949, 212-37. The behavior of polyvinyl ethers and their salts, on metallic films, was examined by the method of blowing them off a polished plate by means of a collimated air stream (cf. C.A. 43, 2130a). Polyvinyl butyl ether and related substances, in air and in solution, usually show an increase in viscosity with increased distance from a solid surface; the effect may attain 2-4 fold magnitude and extends to 5 μ or beyond. Similar behavior of instability type is shown by a wedge-shaped film of these polymers. Max. instability is found at intermediate concns., which are generally lower with higher mol. wt. of the polymer. In contrast to common liquids these polymers show instability as a result of shear with film flow; the effect is greater, the longer is the contact of the polymer with the metal. The instability phenomenon is little affected by temp. The results are explicable on the basis of mol. orientation at the interface. The results are shown graphically. G. M. Kozolapoff

DERYAGIN B.V.

A new method of measuring the specific surface of porous substances and powders. B. V. Deryagin. Akad. Nauk. S.S.R. Trudy Inst. Fiz. Khim. No. 1, Novye Metody Fiz. Khim. Issledovani. Poljarknost. Vydelen. 150-4(1930).—An app. is described, which is first evacuated, and then filled with a certain amt. of air, which is measured by aid of a thermometer. If this app. contains a porous material, the air will filter through it and the pressure found will be different at various times. Two manometers are provided, one with oil for low pressures, the other with Hg for high pressures. Values are presented and compared with those obtained by other methods; thus, e.g. apatite will show from 0.91 to 49.0×10^3 sq. m./g., depending upon the mesh, whereas the MeOH-adsorption method furnished 0.1×10^3 sq.m./g. for the finest mesh. ZnO showed values of 0.57 by this method, 2.7 by N adsorption, and 0.18 sq.m./g. by the dye-adsorption method. Other materials used in the measurements were corundum, BaSO₄, soil, silica gel, and concrete.

"Adhesion of Quartz Filaments in Aqueous Media," A. D. Malkina, B. V. Deryagin, Inst of Phys Chem, Acad Sci USSR, Lab of Surface Forces

"Kolloid Zhur" Vol XIII, No 6, pp 431-447

Measured adhesion of fine quartz filaments in aqueous media using Deryagin's formula to calculate specific adhesion energy. Values obtained correspond closely to Bradley's for adhesion of quartz spheres in air. In air adhesion energy is independent of duration of contact; in water it grows slowly from zero to equilibrium value approximately equal to value in air. Time for reaching equilibrium value is decreased by addition of electrolytes (increased cation charge) and as temperature is increased. Between 30-43°C this time drops sharply from days to 1 hr. Adhesion kinetics are not affected by time of filament immersion prior to contact or any force pressing them together. Slow separation requires 10-15% less force than rapid. Apparently hydrate layers covering filaments are gradually "destroyed" after contact period. Absence of these kinetics for contact in air and similarity of specific energies for contact in water and in air indicate in both cases filament surfaces enter into "direct" contact or are separated by identical boundary layer of water. Addition of high concentration of acetone stabilizes hydrate layers and reduces adhesion energy to zero. Explains effect of solvation on lyophilic dispersed systems and has applications in technological processes.

Apparatus for determination of the coefficients of diffusion of vapors of liquids in the atmosphere. N. V. Dzunashvili, P. M. Prokhorov, and A. D. Malkina (Acad. Sci. U.S.S.R.), Zemstvosye Lab. 10, 502 3(1950); cf. C.I. 44, 8184g.—The app. consists of a vessel provided with a horizontal porous separator. The test liquid is introduced into the bottom compartment, while air or other gas is circulated through the upper compartment. Both air spaces are connected to a differential manometer, with 3-way stopcock switching. The differential pressure read on the manometer is proportional to the vapor pressure difference on the 2 sides of the porous barrier. Tests with acetone, C_2H_5 , benzene, and MgO gave satisfactory results. G. M. Kunkapoff

New diffusion manometric instruments for measuring diffusion coefficients, volatility, and vapor content of various liquids in the atmosphere. [J. V. Bikerman, S. P. Pukinskaya, and A. D. Malkova (Acad. Sci. USSR), Zhur. Khim. Akad. Nauk SSSR, 1961, 37, No. 1, p. 111.] A chamber containing satd. vapor is sep'd. by a porous membrane (porosity 1-3%) from a chamber in which the vapor pressure p (atm) is kept very low by an air current. In steady state, the pressure difference between the 2 chambers at first approx. is $\frac{1}{2}D(\rho - \bar{\rho}) / kT$, D is the diffusion coeff. of the vapor, $\bar{\rho}$ viscosity of the air-vapor mixt., ρ the pressure of the satd. vapor, T the pressure in the air chamber, and K the app. const. The following D were obtained at 0° and 20°: Me₂O 0.1070 and 0.1120; benzene 0.0841 and 0.0900; Methyl 0.1214 and 0.1308; and CCl₄ 0.1230 and 0.1424 cm.²/sec. Another method makes the knowledge of $\bar{\rho}$ unnecessary. The instrument can be used also for detg. vapor pressures (if D is known), the product $D\rho$, which dets. the rate of evapn., and the rate of thermal diffusion of vapors. [J. J. Bikerman]

CA

New methods of measurement of specific surface (in sq. cm./g.) and specific adsorption (in g./sq. cm.), I. D. V. Duryagin, V. I. Krylov, and P. M. Fridlyand (Izdat. Fiz.-Chim. Akad. Nauk U.S.S.R., Moscow). Zhur. Fiz. Khim. 24, 1371-83 (1950); cf. C.A. 43, 1872. The method utilizes the Knudsen flow of a rarefied gas through a plug of porous or nonporous disperse material the sp. surface of which has to be determined. Gas-kinetic theory leads to the formula $Q = \frac{4\pi\delta}{3} \frac{\Delta p}{\Delta t}$, where Q is the flow rate per unit surface of a gas experiencing a pressure drop Δp over a length Δt of material and δ is given by $\delta = A(2\pi)^{1/2} \cdot (\theta/S_0 M k T)^{-1/2}$; S_0 is the sp. surface; A is the ratio of pore vol. to total vol. of material; M is the mol. wt. of the flowing gas; A is equal to $8/3$ or $24/13$ according to the ductility or nonelasticity of the gas mol. collisions with the pore walls. The theory, app., and expts. are described in detail (cf. C.A. 41, 2636). For nonporous adsorbents, Duryagin's method gives results in agreement with the ones given by more elaborate standard procedures. With porous adsorbents, the method which does not measure the surface of dead-end pores gives low values, e.g. silica gel: Duryagin 14.2, B.E.T. 50 sq. cm./g. A crit. expt. consists in measuring the sp. surface of a mixt. of 5 different powders of known sp. surface: the observed value (11.7) checks well with the value calcd. from the mixt. compn. (11.9). The method seems promising for routine quick tests. (soil, soils, fertilizers, etc.). Michel Boultar

Principal Laws Governing the Movement of Water in Soil Under Various
Wetting

The authors generalize the problems developed in an earlier published work of theirs (Gidrotakhnika i melioratsiva, No. 2, 1950), and also present some new information. They give values of the "kinetic" specific surface of certain grounds and soils (determined by V. I. Krylova by measuring the resistance to movement of gases through them). They consider the earlier proposed equation for the determination of the velocity of motion of the wetting front (B. V. Deryagin, Kolloid. zhur. 8, No. 1-2, 1946), based on the empirical connection of Kozeny between permeability and porosity and on the assumption concerning the complete filling by liquid of the region behind the moving wetting front. The quantity "capillary motion" at the front of wetting is expressed by means of "kinetic" specific surface, and not by meniscus radius (as done earlier). ✓ Investigation of gasous discharge on tearing of high-polymer film from hard backing. V. V. Karasy, N. A.

Nikrova, and B. V. Deryagin. Dokl. Akad. Nauk SSSR, 80, No. 11, 1948. Various films of benzylcellulose, acetobenzaldehyde, para-phenol, carbonaceous, and polyvinyl chloride can obtain a luminous discharge when torn from a backing of crown glass at gas pressures not less than 0.1 mm. Hg and at rates not less than 10⁻³ cm./sec. with the

exception of polyvinyl chloride which yielded bright sparks every 2-4 sec. at a tearing rate of 10⁻⁴ cm./sec. Discharge spectra were characteristic of the gas present and the substance under test. The discharge potential approximated the equation of Paschen, $V = R(\rho h)$ where V = discharge potential, ρ = gas pressure, h = discharge gap. Observation supported the elec. theory of adhesion previously published by the authors (cf. C.A. 43, 2812).

Dokl. Akad. Nauk SSSR, 90, No. 6, 1055-8 (1953) In Russian.

A method has been designed for measuring intermolecular forces at large distances by determining the equivalent molecular attraction between the plane surface of a plate attached on one arm of the balance beam and the convex surface of a lens placed very close above the plate. The very high sensitivity required was attained by attaching to the balance beam (35 mm long and 0.1 g in weight) a frame with 20 wire turns, arranged below a permanent magnet. A current from a photoelectric-cell system, tracking the movement of the beam, was passed through the wire of the frame. The negative feedback regulating system

Authors describe a method for drying thin sheets by placing sheet with wet film between a heat-radiating screen and a cold condenser plate. Thermal gradient perpendicular to film surface sets up circular air-convection currents between sheet and condenser, carrying moisture to the condenser. From similarity of mass and heat transfer, authors derive a relation for rate of moisture transfer in terms of nondimensional parameters. Only one experimental value is given, and this is twice as large as that predicted. Authors explain discrepancy qualitatively by discussing: (a) travel of dust particles which always move in direction of temperature drop, carrying with them additional moisture, and (b) effect of supersaturation. Authors : Deryagin, B. V., Memb. Corresp. of Acad. of Sc. USSR

Title : Problems of adhesion

Periodical : Vest. AN SSSR 7, 10-21, July 1954

Abstract : The physical aspects of adhesion, which takes place during the contact of two solid bodies in the presence of an external gaseous or liquid medium, are discussed. It was determined, through practice, that adhesion depends largely upon the nature of the functional groups included in the composition of the adhesive layer as well as upon the chemically active atoms and radicals present in this layer. The effect of individual active-atoms or groups of atoms, which are present in the adhesive layer and may enter into an electron chemical bond on the conversion of electrons from one phase into another, is explained. ✓ Theory of heterocoagulation, interaction, and mutual adhesion of different particles in electrolytic solutions. B. V. Derygin (Inst. Phys. Chem., Acad. Sci. U.S.S.R., Moscow). *Kolloid Zhar.* 16, 426-38; *Colloid J. (U.S.S.R.)* 16, 403-15(1954) (English translation); cf. following abstr.— The interaction of two diffuse elec. double layers is calcd. for an asym. binary electrolyte. Curves for potential as function of the distances between two charged walls, at a given value of the interaction, are shown. When the potentials of the 2 walls are const. and have identical signs, gradual mutual approach of the walls first causes repulsion which reaches a max. and decreases to zero; on a further approach, the walls attract each other, and the attraction increases to infinity when the distance tends to zero. The max. value of the repulsion depends on the smaller of the 2 potentials only; this is true also when the walls are neither plane nor parallel. When the 2 potentials have opposite signs, the walls attract each other at any distance. Approximations for small potentials are calcd. Introduction of van der Waals' forces leads to the rules: (1) when these forces cause a repulsion between 2 particles in an ionic soln., the particles can adhere to each other only if they carry potentials of 2 opposite signs; (2) when these potentials are high, adhesion can occur only in dil. solns. The theory explains adherence of Hg to glass in salt solns., dyeing in the absence of coagulation; etc. J. J. Bikerman

Title : Adhesion of high-polymers to glass and its dependence upon pressure and nature of the surrounding gas medium

Periodical : Dokl. AN SSSR, 97, Ed. 3, 475 - 478, July 21, 1954

Abstract : A method of determining the discharge potential, discharge gaps and surface density of electrization, by studying the polymer-glass adhesiograms, is described. The effect of pressure and nature of the surrounding gas on the adhesion of high-polymers to glass was determined by the Paschen law. By studying the effect of various factors, including the molecular structure of the adhesive and liner, it is possible to make a rational selection of gluing and lacquer forming polymers and form conditions increasing the adhesion. Title : Optical investigation of the adsorption and surface condensation
of vapors close to the saturation point

Periodical : Dok. AN SSSR 98/1, 93-96, Sep 1, 1954

Abstract : Polymolecular adsorption and condensation of vapors of n-alcohols,
water, CCl_4 , benzene, etc., on smooth surfaces were investigated
to determine the phase conversions taking place between the
volume and liquid layers close to the wall of the test vessel.
The device used in this optical investigation is described. The
adsorption on smooth surfaces in a range of relative pressures
higher than 0.95 - 0.97, was found to be of a polymolecular
nature. In other pressure ranges the adsorption acquires a
mono- or bimolecular nature. Ten references: 9-USSR and 1-German

Title : Theory of repelling forces in electrolyte layers between non-uniformly charged surfaces

Periodical : Dok. AN SSSR 98/6, 985-988, October 21, 1954

Abstract : The development of an ion-electrostatic theory, regarding the repulsion forces in electrolyte layers between uniformly and non-uniformly charged surfaces, is discussed. The formulation of the first quantitative physical-theory, of the stability of lyophobic colloids and dispersion systems, is described. Formulas, determining the repulsion forces in electrolyte layers, are included. Eight references: 6-USSR and 2-USA (1937-1953). Graphs.

Title : Equilibrium, stability and kinetics of free liquid films

Periodical : Dok. AN SSSR 99/6, 1029-1032, Dec 21, 1954

Abstract : The method and mathematical formulas applied in determining the equilibrium, stability and kinetics of free liquid films, are described. The stability of a liquid film investigated in this report pertains to the rupture or sharp increase in the thickness of the film down to such values where the stability of the film can be secured by its elasticity connected with the properties of adsorption mono-layers. Equilibrium of the film was found to be of a timely nature depending upon the kinetic process of slow settling of the film up to a point when it reaches a critical thickness at which it loses its stability.
