Title : Vitamin B₁₂ Metabolism in Subtropical Anemias.

Orig Pub : Tr. Stalinab. med. in-ta, 1955, 16, 63-75

Abstract : In patients with blood and liver diseases, the levels of vitamin B₁₂ in blood and urine were microbiologically determined; some of the patients received a load of 15 μ of the vitamin. In a control group, not including blood and liver patients, the 24-hour urine contained 20-60 m μ of vitamin B₁₂, at a 140-340 μ γ /ml of Vitamin B₁₂ level in the serum (S) and a daily fluctuation of this level of 20-60 μ γ /ml. Loading with B₁₂ produced an increase of the amount of the vitamin in the S after

Title OXIDATIVE METABOLISM OF *STAPHYLOCOCCUS AUREUS* AND OF ITS MUTANT OBTAINED BY UV-IRRADIATION

Periodical: *Biokhimiya*, v. 27, no. 1, 1962, 109-119

Text: The *S. aureus* mutant (St-VV-3) shows sensitivity to carcinostatic substances. It was therefore of interest to compare the pathways of oxidative metabolism in the mutant and the parent strain (St-209) and to see whether the mutant could be considered as a model of a cancerous cell. The parent strain St-209 showed a high O₂ uptake in the presence of glucose, also oxidizing pyruvate, lactate, acetaldehyde, formaldehyde, ethanol, formic acid, OAA and malate. Under anaerobic conditions St-209 actively decarboxylated pyruvate and OAA. Monoiodoacetate (0.2 mM) completely inhibited the utilization of glucose and accumulation of lactate by St-209. In contrast to the parent strain, St-UV-3 showed no increase in oxygen uptake in the presence of glucose, but unlike the former, was able to oxidize a number of TCA cycle intermediates. Under anaerobic conditions St-UV-3 exhibited only slight pyruvic and OAA decarboxylation. The Q_{CO_2}/Q_{O_2} ratio for pyruvate was higher than 2 in strain St-209, while in St-UV-3 it was close to 1. The effect of arsenite,

malonate, cyanide and orthophosphate on the oxidation of different substrates by the two strains was compared. The results are discussed in terms of the possible defect imparted to the respiratory system of St-UV-3 as a result of mutation. The properties of the respiratory system of the mutant are compared with those of tumor cells.

TITLE: Effect of impact acceleration on nitrogen metabolism in the rat brain

SOURCE: Voprosy meditsinskoj khimii, v. 12, no. 3, 1966, 262-265

TOPIC TAGS: impact acceleration, animal physiology, acceleration, nitrogen metabolism

ABSTRACT: Ninety white laboratory rats (weight 130—160 g) were used to determine the effect of impact acceleration on the metabolic processes of the brain. The concentrations of free ammonia, glutamine, glutamate, asparaginate, and γ -aminobutyric acid, as well as of labile and stable bound amide group proteins were investigated. The rats were subjected to impact accelerations (250—300 m/sec²) in a chamber. These accelerations were arbitrarily designated as: weak (4—10 G), medium (11—24 G), and strong (>24 G). Three of the ten rats subjected to strong impact acceleration died. The rats were immersed in liquid air 15—20 min after exposure and the frozen brain, excluding the cerebellum, was removed. The meninges were removed, the brain was pulverized in liquid air, and was transferred in a powdery form for precipitation of

SOURCE: Voprosy meditsinskoj khimii, v. 12, no. 4, 1966, 418-424

TOPIC TAGS: brain metabolism, liver metabolism, combined stress, hyperoxia, phosphorus metabolism, oxidative phosphorylation, *LIVER, RAT, BIOLOGIC RESPIRATION, BRAIN, BIOLOGIC METABOLISM, PHOSPHATE, OXYGEN*

ABSTRACT: L-methionine-sulfoximin (MSI) alters the content of adenylic components in the liver of rats. Six hr after MSI injection, the ADP and ATP content increases (30%), oxidative phosphorylation increases, and respiration is unaltered. Twelve hr after MSI injection there is an increase in the total content of adenylic system components. MSI does not alter the intensity of brain metabolism but depresses esterification of inorganic phosphates (34%). Exposure to oxygen under pressure (4 atm) for an hour increases both respiratory intensity and brain phosphorylation. MSI and increased oxygen pressure together caused an activation of brain phosphoryla-

ACC NR: AP6025929

0

tion compared to the action of MSI alone. The sensitivity of animals injected with MSI to increased oxygen pressure is elevated compared to controls. Apparently, one reason for this is altered phosphorus metabolism. It was concluded that despite the ability of increased oxygen pressure and MSI to precipitate convulsive attacks, their mechanism of action on the phosphorus metabolism of individual tissues differs. TITLE: The role of space redistribution of charges in the kinetics
of the inner photoeffect of highly resistant semiconductors

PERIODICAL: Fizika tverdogo tela, v. 3, no. 5, 1961, 1384 - 1392

TEXT: The following problem is treated in this paper. In inhomogeneous photoconductors or on inhomogeneous exposure of the photoconductor the transition to a new state of equilibrium is accompanied by a redistribution (RD) of the density of the charged carriers. This RD is of importance for the construction of television tubes and for the study of the kinetics of high resistance photoconductors. From these considerations the sluggishness of the photocurrent was measured on exposure of layers of $Sb_2S_3 \cdot Sb_2Se_3$, amorphous Se, Sb_2S_3 , $AsSbSe_3$, PbO and some mixtures of these. The sensitivity to light of these highly resistant substances ($\rho = 10^{11} - 10^{14}$ ohm.cm) was so great that the resistance decreased to one hundredth of the dark resistance on exposure to 400 lux. The exposure

Card 1/6

23107

B101/B214

The role of space redistribution...

was made through KC-10 (KS-10) red filter or ϕ C-1 (FS-1) violet filter. The sluggishness was measured along and perpendicularly to the layer. The exposure was made in the interval of $2 \cdot 10^{-2}$ sec periodically by means of a toothed disk or once (1 sec) by means of a shutter. The following quantities were measured: the time constant τ_{eff} determined as the ratio between the maximum and the minimum photocurrent in periodic impulses and the "front constant" τ_f . The experimental data showed strong scattering.

1) Sluggishness independent of the applied potential. Fig. 4 shows the results of measurements for Sb_2S_3 , Sb_2Se_3 . The sluggishness along and perpendicular to the layer had about the same value whether exposed to red violet or white light. Similar results were obtained with other substances also. From this it is concluded that inspite of greatly varied experimental conditions with regard to RD no great difference in the kinetics of the inner photoeffect appeared. Therefore, the RD has only a small effect on the kinetics of the change of conductivity. 2) Sluggishness dependent on the potential applied to the sample. This case appears a) in samples whose ratio of resistivities for different signs of the potential is particularly large (about 40 for $U = \pm 1$ v); b) when the
Card 2/6

The role of space redistribution...

S/181/61/003/005/012/042
B101/B214

exposure is made from the side of the aluminum electrode. Fig. 6 shows the results of measurements for a $Sb_2S_3 \cdot Sb_2Se_3$ layer. It is concluded that the dependence of the sluggishness on the potential is due to the contact effect on the Al electrode. Also the observed jump in the sluggishness when the potential passes through zero (Fig. 9) shows that the change in the kinetics is caused by contact effects. V. I. Il'ichev and G. N. Travleyev, students of LGU (Leningrad State University), assisted in the work. Ya. A. Oksman and M. V. Yepifanov are mentioned. There are 9 figures and 12 references: 6 Soviet-bloc and 6 non-Soviet-bloc. The 4 references to English-language publications read as follows: R. V. Smith, Rose, Phys. Rev., 97, 1531, 1955; A. Rose, *ibid.* 97, 1538, 1955; J. R. Haynes, J. A. Hornbeck, *ibid.* 97, no. 2, 311, 1955; G. J. Shulman, *ibid.*, 102, no. 6, 1451.

Text Data

Coverage: The most effective modern method of treatment of concrete is described. This method consists in the removal of excess water and vapor by the creation of a vacuum above the concrete hardening in the forms. The method is widely used in the construction of dams and large foundations for improvement of the quality of concrete and extension of its durability, particularly under winter conditions. This method has been used in recent Soviet hydro-electric constructions.

AUTHORS: Gershberg, R.Ye. and Fronik, V.I

TITLE: The absolute spectrophotometry of the nebula NGC 7000 by means of light filters

PERIODICAL: Referativnyy zhurnal, Astronomiya i Geodeziya, no. 3, 1951, 29, abstract 3A282 ("Izv. Krymsk. astrofiz. observ.", 1959, v. 21, 21-228, Engl. summary)

TEXT: The authors describe the methods of photographic observations of diffuse emission nebulae and present the results of investigation of the nebula NGC 7000. They determined absolute intensities of nebula emission in the lines $\lambda 3727$, N_1+N_2 , $H\beta$ and $H\alpha+[N II]$, and in continuous emission near $\lambda 6700$. The stripping out of the mentioned regions was performed by means of glass light filters. The contours of pass bands are given. Observations were conducted with a camera $D = 640$ mm, $D/F = 1:1$. The calibration of the photographs was made by a tubular photometer. Standardization was carried out by references to ordinary stellar images obtained with an auxiliary camera installed on the device. The energy fluxes from the standard stars were determined from the energy distribution in

The absolute spectrophotometry ...

spectra of stars of different spectral classes with respect to the Sun. The accuracy of emission intensity determination in absolute magnitudes amounts to $\sim 20\%$. The changes in emission line intensities and continuous spectrum of the nebula were obtained along the selected cross sections and in the bright filaments. It is shown that continuous emission of the nebula is mainly caused by the background of weak stars not resolved by the photoemission. Electronic temperature was determined from the ratios $[O II]/H\beta$ and $[O III]/H\beta$. It does not practically change at the transition from the zone of O III to the zone of O II; it also does not increase in bright filaments which are sharp edges of [O III]-emission. The enhanced brightness of continuous emission near the bright filaments can be explained by the recombination mechanism of hydrogen emission. The star HD 193579 (O7) is the star exciting the northern part of the nebula. However, it is not able to ionize the whole set of nebulae in this field. It is presumed that one more exciting star or a group of stars exist between the "Pelican" and "America" in the field of the "Mexican Bay", hidden from observation by a dense dust cloud. It is noted that the exciting star must be located very near the curvature center of a large arc-shaped filament at the nebula eastern edge. From the absence of stars of spectral classes O or B0 up to 12^m in this field, the authors estimate the density and mass of the absorbing cloud. The lower limit of absorption in the cloud is 6^m , and its mass amounts to

TITLE: Photographing diffuse nebulae in infrared rays

PERIODICAL: Referativnyy zhurnal. Astronomiya : Geodeziya, no. 4, 1961, 30, abstract 4A321 ("Izv. Krymsk. astrofiz. observ.", 1960, v. 22, 150-151, Engl. summary)

TEXT: The authors report on the results of photographing bright gaseous nebulae NGC 6611, 6618 and 6623 in infrared region by means of an electronic-optical converter mounted on a high-speed camera with D=640 mm, D/F=1:1.4. It was supposed to detect emission in region $\lambda\lambda 9060-9540$. The region was singled out by a filter absorbing light with $\lambda < 8000$ and by the long wavelength sensitivity border of the equipment. A 3C -7 (2S-7) additional filter permitted the solution of the problem about the nature of emission, i.e. emission [S III] or continuum, because by narrowing the pass band by 2.5 times the filter did not practically change transmission of emission at $\lambda 9540$. No emission from the nebula NGC 6611 was

TITLE: On the Fine Filamentous Structure and Polarization of Reflection
Nebulae

PERIODICAL: "Izv.Krymsk.astrofiz.observ.", 1960, Vol.23, pp.21-30 (Engl.summary)

TEXT: The author describes characteristics of fine filamentous reflection
nebulae in Pleiades. He discusses the nature of non-radial (relative to the light-
ing stars) light polarization of these objects. Physical mechanisms are considered
which could explain the formation of such extended structures in clouds of H I. Ap-
parently these filaments can not be formed in the development course of an indivi-
dual cloud, and the picture observed may prove to be a result of lighting by bright
stars of the fine filamentous structure inherent to extensive regions of H I. There

TITLE: Expansion of H II regions and origination of peripheral structures
in diffuse nebulae

PERIODICAL: Referativnyy zhurnal, *Astronomiya i Geodeziya*, no. 7, 1962, 35,
abstract 7A266 ("Izv. Krymsk. astrofiz. observ.", 1961, v. 25, 76 -
87; English summary)

TEXT: The author considers phenomena proceeding during expansion of an
ionized hydrogen zone surrounding a hot star. A shock wave is propagated over
the H I region, and in the H II zone density decreases. On account of density
decrease, the boundary between the ionized and non-ionized regions (ionization
front) moves away from the star. The problem is solved on assumption of iso-
thermicity for the case of uniform expansion of the H II zone. An investigation
of the condensed gas layer at the boundary of regions H I and H II has shown
that it can shine like peripheral structures (glowing arcs) observed in several
diffuse nebulae. The author holds that peripheral structures of the IC 1805,
IC 1848 nebulae are of just this nature. ✓

TITLE: On temperature in the transition region of interstellar medium
between zones of H II and H I

PERIODICAL: Referativnyy zhurnal, *Astronomiya i Geodeziya*, no. 7, 1962, 35 - 36,
abstract 7A267 ("*Izv. Krymsk. astrofiz. observ.*", 1961, v. 26,
324 - 341)

TEXT: The author considers problems connected with determination of electron temperature in the transition region of interstellar medium between zones of H II and H I. He investigates the dependence of the average energy of photo-electron, formed in the radiation field of a hot star during ionization of interstellar hydrogen, on the optical thickness τ . One-dimensional problem is solved rigorously. For the plane problem a rough approximation has been found. It is shown that effect of scattered L α -radiation sharply reduces the ϵ increase with τ , and this effect very little depends on the temperature of scattering medium within the range from 2,000 to 14,000°K. At $\tau \approx 1.5$ a con-

Card 1/2

On temperature in...

siderable part of photoionizations is produced by scattered Ly- α quanta, and at $\lambda \approx 10$ even the overwhelming part. All calculations are conducted for two models of early stars O7-O8 and B0-B1 V. Emission efficiency of various forbidden lines in cooling interstellar medium is estimated. It is shown that submillimeter radiation of neutral oxygen atoms is comparable in this respect with radiation of ions of carbon and silicon (in H I zones and in the H II - H I transition region). The author presents the results of determining electron temperature in the outer structural details, bright rims and "drapery", of the diffuse nebula NGC 6523. No marked difference was detected between temperatures of these formations and those of innermost parts of the nebula. There are 27 references.

AUTHOR: Gershberg, R.Ye.

TITLE: On the association between filamentary nebulae which are remnants of the envelopes of type II supernovae and H_α-emission stars

PERIODICAL: Astronomicheskiy zhurnal, v. 39, no. 6, 1962, 1033 - 1037

TEXT: The association was first discovered by N.V. Dolidze (Astron. tsirk. no. 203, 8; no. 204, 13, 1959; Byull. Abastumanskoj astrofiz. observ., 25, 105, 111, 1960). There are three possibilities as far as the interpretation of this association is concerned, namely: 1) stars with different masses may be simultaneously formed in stellar clusters and whilst the heaviest of them evolve rapidly through the hot-star stage and explode as supernovae, the lighter stars have not as yet reached the main sequence; 2) the effect may be associated with phenomena analogous to the Earth's radiation belts - the upper layers of the field stars may be disturbed by the supernova envelope travelling through them, and 3) the phenomenon may be described in terms of the
Card 1/2

On the association

5/033/62/039/006/013/024
E032/E314

physical nature and evolution of compact details in the peculiar nebulae connected with the Cas A radiation source which might play the role of "protostars". The compact formations might in time evolve into H_α-emission stars since S.B. Pikel'ner (Astron. zh., 38, 21, 1961)⁰ has interpreted them as accumulations of interstellar matter. It is shown that the latter interpretation is possible but further photometric and spectrophotometric data will be required to elucidate the physical conditions in nebular objects connected with Cas A. ✓

TITLE: Radio emission of planetary nebulae and a determination of the distance to these objects

SOURCE: Akademiya nauk SSSR. Krymskaya astrofizicheskiy observatoriya. Izvestiya. v.28. 1962. 159-165

TEXT: The distance determination is based on the following formula:

$$R = 1.85 \cdot 10^{40} \frac{F_{\nu}}{\varphi^3 n_e^2} \quad (8)$$

where: R is in pc, φ is the angular diameter in seconds, F_{ν} is the flux density in W/m^2 cps ($T_e = 15\ 000\ ^\circ K$), and n_e is the electron density. The method may be used for radio-transparent nebulae and is not sensitive to their optical thickness in the Lyman continuum. In the above formula the density may be deduced independently of distance (M.J. Seaton, D.E. Osterbrock, *Astrophys.J.*, 125, 1957, 66). The table shows some of the

TITLE: Energy distribution in the continuous spectrum of novalike and symbiotic stars

CITED SOURCE: *Izv. Kry'msk. astrofiz. observ.*, v. 30, 1963, 25-41

TOPIC TAGS: star, symbiotic star, novalike star, astronomy, astrophysics, stellar spectrophotometry, slitless spectrograph, emission line, nebula, planetary nebula

TRANSLATION: This article presents the first results of stellar spectrophotometric studies made using the 2.6-m reflector of the Crimean Astrophysical Observatory. There is a brief description of the slitless spectrograph used in the observations and a detailed discussion of the method used for investigation of the energy distribution in the stellar continuous

Card 1/3

ACCESSION NR: AR4039237

spectrum. On the basis of 30 spectrograms the authors obtained the energy distribution in the spectrum of the novalike star AG Dra and in the spectra of three symbiotic stars (Z And, AG Peg and BF Cyg). For each of these stars the authors determined the energy distribution in the spectral region $\lambda \lambda$ 3300-5000 and have given a physical interpretation of the observed distribution. The spectrum of AG Dra corresponds to the integrated spectrum of a star with a spectrophotometric temperature of 2800°K and ionized hydrogen at $T_e = 20000^\circ\text{K}$; the spectrum of Z And is interpreted as the joint radiation of a star with $T = 36000^\circ\text{K}$ and hydrogen plasma at an electron temperature of 30000°K. The spectra of AG Peg and BF Cyg in the studied region of the spectrum are caused by the luminescence of ionized hydrogen at electron temperatures of 30000 and 80000°K respectively. An estimate is made of the optical thicknesses of all gas components of the studied objects; in the H δ line they are several units. Estimates are given of the equivalent widths of the brightest emission lines and the determined energy distribution in the continuous spectrum has been used to compute the energy relationships between the emission lines. A preliminary quantitative analysis of the emission lines made for BF Cyg confirms the results obtained from the continuous spectrum. Investigation of the planetary

TITLE: Investigation of emission nebula NGC 6618. Outburst of supernovae, and diffuse nebulae

CITED SOURCE: Izv. Kry'msk. astrofiz. observ., v. 30, 1963, 90-103

TOPIC TAGS: supernova, emission nebula, nebula, interstellar absorption, diffuse nebula

TRANSLATION: Arguments are given in favor of the assumption of the relatively recent outbursts of Type II supernovae in nebula NGC 6618. First, according to observation data, spectrum of glow of this object should be of thermal nature. However, the 5 stars (brighter than 12^m) of classes O-B known in this region cannot ensure sufficient ionization of this powerful gaseous complex. Therefore it is necessary to assume the presence of unregistered O-B stars with a brightness

Card 1/3

ACCESSION NR: AR4042151

weaker than $12^m.5$. Re-evaluation of the distances to O-B stars known in a given region of the sky, based on the presence of systematic divergences of the MK spectral classification and that given by I. I. Pronik (Journal of Abstracts, Astronomy, 1961, 4A407; 1962, 1A265), and also determination of the distance to NGC 6618 by radioastronomy data, taking into account not only circular but also radial motions of the gaseous component of the Galaxy, lead to coinciding values of ~ 300 ps. The presence, in the region of the radio-center of the nebula, of interstellar absorption $\geq 11^m$, explains the absence, in the catalogs, of O-B stars ($12^m.5$), since the absolute value of the latter is only $\sim 7^m$. Second, near NGC 6618 there are known 3 stars of classes O-B with tangential velocity components of the order of 220 ± 190 , 310 ± 160 , and 390 ± 160 km/sec; the region of "emanation" of these is inside the nebula. Their kinematic ages are within the limits $(1.4 - 2.2) \cdot 10^4$ years. Third, photographs in H α , made with long exposure, show that emission nebulae IC 4706, IC 4707, and S 193, encompassing the bright central part of NGC 6618 from the west, are closed with a luminescent semiellipse, encompassing this object from the east. All this leads to the conclusion con-

cerning the close similarity of the complex NGC 6618 with the corresponding known complex in the Orion nebula and gives an idea of their formation as a result of some catastrophic phenomenon, similar to or even identical with outbursts of Type II supernovae. If, however, we assume identity of the mechanisms of the formation of envelopes of NGC 6618 and the Barnard loop (envelope of the complex in Orion), then it is possible to estimate the age of the former. This age is equal to $\sim 10^5$ years. Considering the coarseness of the determination of the age of the envelope of NGC 6618 and the kinematic ages of its "scattering" stars, these magnitudes can be considered as agreeing fully satisfactorily. Furthermore, it is possible to estimate the electron concentration in the envelope of NGC 6618, which is $n_e \sim 80 \text{ cm}^{-3}$. The conclusion is drawn that apparently, as a result of outbursts of supernovae inside diffuse nebulae, in the latter there should appear extended weakly luminescent emission fields with the possible formation, in the central parts, of large emission complexes of dark absorbing interstellar matter and that outbursts of supernovae can support random motions of matter inside diffuse nebulae.
