TITLE:

Glass Industry in Soviet Belorussia (Stekol'naya
promyshlennost' Sovetskoy Belorusssii)

PERIODICAL:

Steklo i keramika, 1959, Nr. 2, pp. 1-4 (USSR)

ABSTRACT:

In the present paper the author describes the primitive working methods and the small production volume of Belorussia's glass industry in the time before World War I. This and World War II brought an almost complete destruction of this industry. In the years from 1946 to 1950 Belorussia's glass works were equipped with modern furnaces and machines that increased their production considerably. The construction of two large glass-works began in 1954. The glass works "Oktyabr" were modernized. The plant in Nove-Borisov (imeni Dzerzhinskii) introduced the automatic machine VS-2a for the production of thin-walled drinking glasses thus achieving a considerable increase in production. In the years from 1959 to 1961 the Republic's glass works are to be extensively mechanized and automatized, and the assembly line procedure is to be introduced for the production of tableware. Also the variety of products is to be enriched from clear glass, colored glass products.

factory). The Somel factory is continuing the production of polished reinforced glass tubes and the development of glass tubes. The Belarussian glass industry's output prediction is to be doubled by 1985 as compared to 1980.

Explosive properties of mixtures of inert salts with nitroglycerin. A. I. Goldbinder. *Doklady Akad. Nauk S.S.R.* 50, 100-200(1943). - Mixts. of 15% nitroglycerin with 85% of the salt sifted through 20 mesh sq. cm., packed in paper tubes of 30-32 mm. diam., were detonated and the max. distance over which the detonation could be transmitted to an identical charge, placed on dry sand, was detd. This distance was 25 cm. for NH₄Cl, 11 for NaCl, 10 for NaHCO₃; (NH₄)₂SO₄, (NH₄)₂CO₃, talcum, and chalk do not transmit the detonation even in end-to-end contact. In the case of NaCl, the effect of the particle size is illustrated by the data: av. length of crystals 0.06, 0.09, 0.10-0.12, 0.16, 0.38 mm., max. distance 0, 6, 12, 9, 5 cm.; there is, consequently, an optimum grain size irrespective of the crystal size, mixts. with 85% NaCl never exceed 12 cm. as max. distance of transmission of detonation, whereas NH₄Cl attains 25 cm. Ability to transmit detonation at a distance seems to be linked with the ability of the salt to exclude the nitroglycerin in the form of drops; however, addn. of 10% of talcum or chalk, which absorb the liquid, does not impair the detonation-propagating ability. Slight gelatinization of the nitroglycerin will also prevent evaporation but, at the same time, it decreases somewhat the max. distance. - N. Thon

"Function of Inert Salts in the Composition of Safety Explosives," A. I. Gol'binder, Moscow Sci Res Inst Safety in Mining Operations, 2 $\frac{1}{2}$ pp

"Dok Akad Nauk SSSR, Nova Ser" Vol LIX, No 2

Results of experiments show that hypotheses relating the role of inert salts in composition of safety explosives only to the absorption of heat erroneous, and that in processes of ignition the chemical nature of the inert salts also shows influence. Makes some remarks on character of influence. Submitted by Academician N. N. Semenov, 6 Nov 1947.

TITLE: On the Probable Means of Expressing the Mean Value of Probabilities

PERIODICALS RECEIVED IN JULY 1922. Vol. 12, No. 1256. Page 1

ABSTRACT.

The apparatus used in this experiment consists of a glass vessel containing the reaction mixture, which is a suspension of the polymer in benzene solution. The vessel is connected to a gas cylinder by a tube, and the gas is passed through the suspension. The gas passes through a porous plate, which is placed in the bottom of the vessel. The gas passes through the suspension, and the polymer is precipitated as a solid. The gas is then removed, and the polymer is washed with benzene. The polymer is then dried in an oven at 100°C.

Oil Well Penetration by Means of Explosives:

SP-7/27-14/17

depth of oil well, n = the number of explosions, A = the coefficient depending on the properties of the explosive and the rock, and the shape of the explosive, and C = the weight of the explosive. The diameter of the penetrative oil well depends on the weight of the explosive charge and this relationship is expressed by $H^m = 10^m$, where $H = \frac{H_1}{n^{1/m}}$, m = exponent slightly less than 1, and B = values ranging from $9 \cdot 10^{-3}$ to $14.5 \cdot 10^{-3}$. Application of explosives in an experimental oil well has disclosed that it is possible to penetrate up to 20 meters at the rate of 0.6 meters per hour, while a turbodrill penetrates about 5 meters of hole at the rate of 0.15 meters per hour. There is 1 Figure, and there are 5 references, of which 4 are Soviet, and 1 is English.

AUTHORS: Gol'binder, A.I. and Ostrovskiy, A.P.

TITLE: Experimental Research on the Blast Drilling of Bore-holes

PERIODICAL: Razvedka i okhrana nadr, 1959, Nr 6, pp 27 - 33
(USSR)

ABSTRACT: The authors describe experimental research on blast drilling of bore-holes drilled in concrete and granite models, to establish certain rules of the efficient blast drilling in deep bore-holes. In the experimental blast drilling of a prospecting bore-hole for Devonian deposits of oil ('Kuybyshevskaya Oblast') in very hard silicified limestones at a depth of over 2500 m, a speed of 0.6 m/hour was achieved. Normal drilling, with a milling cutter, gives only 0.15 m/hour. First, a series of experiments was made to establish the influence of the height of a water column in the bore-hole on the effectiveness of the explosion. It was found (Table 1) that the average

Card 1/4

SCV/121-59-5/16
Experimental Research on the Blast Drilling of Bore-Holes

deepening of the bore-hole with one explosion reaches its maximum in dry bore-holes, and the volume of destruction increases when the bore-hole is filled with water, the height of the water column being equal to 5 - 10 diameters of the bore-hole. A further increase in the height does not increase the volume of destruction. The next series of experiments was made with a constant 6 m height of the water column, but with a variable weight of explosive charges. The results can be expressed in the following equations:

$$1) \Delta h = K_1 (G - g)^{1/3};$$

$$2) h = K_2 G^{1/3} + h_p \quad (\text{so-called Tollik equation and})$$

Card 2/4 3) $\frac{\pi d^2}{4} \Delta h = \Delta V_{sr} = K_3 J,$

SCOV/132-59-6-5/16

Experimental Research on the Blast Drilling of Bore-Holes

where Δh - average deepening with 1 explosion in mm,
G - the explosive charge weight in gr, a - the constant;
 h_2 - the distance between the lower part of the charge
and its gravity center in mm; d - the diameter of the
bore-hole; ΔV_{sr} - average volume of the concrete
crumbled by 1 explosion in milliliters (Table 2).
These results show that for the small charges, the
correlation between the deepening of the bore-hole
and the weight of the blasting charge are positively
reflected in equations 1 and 3. Equation 1 can be
reduced to $\Delta h = K_1 G^{1/3}$. A further series of experi-

ments showed (Table 3) that explosive charges of elongated form give better results than other forms of charges. Another series of experiments was conducted in quarries of different rocks: granite rocks of the Sokolovskiy quarry in the Zhitomirskaya Oblast'; lime-stones - in the Testovo and Podol'sk quarries, Moskovskaya Oblast' and of the clay pits of brick making

Card 3/4

SOV/152-09-5/16
Experimental Research on the Blast Drilling of Bore-Holes

plants of the Moscow region (Table 6). The after-explosion deformation is of three typical types: granites crumble; clays become more compressed; limestones occupy a middle position between the two. In the sub-aqueous explosions, a large part of the rocks is detached from the walls of the bore hole by the action of the produced waves. The comparison (Table 7) of the explosion in a "dry" bore-hole, shows that the volume of destruction in the first bore-hole is 10 times larger than in the dry one. There are 7 tables, 1 photograph, 2 diagrams and 5 Soviet references.

TITLE: Pulsating combustion of liquid explosives thickened with polymer solutions

PERIODICAL: Zhurnal fizicheskoy khimii, v. 35, no. 8, 1961, 1808 - 1812

TEXT: The authors have considered the modification of the burning character of explosives when thickened by means of solutions of high-molecular compounds. Liquid methyl nitrate (MN) uniformly burns at room temperature and at atmospheric pressure at a rate of c. 0.12 cm/sec in glass tubes (diameter 3.8 - 5.3 mm). The combustion pulsates at a viscosity rise obtained by dissolving some polymethyl methacrylate (PMMA). Periods of steady propagation alternate with flame splashing accompanied by whistling sounds; frequency and intensity of pulsation grow with the polymer content. This causes an increase of the average rate of combustion. A moving picture (32 - 100 frames/sec) showed the whole period to consist of a series of equal cycles. The surface first drops slowly, but remains smooth in the process; the rate of combustion is lower than

Card 1/5

Pulsating combustion of...

26547
3/076/51/055/009/011/016
B110/B101 X

that of normal MN (0.08 cm/sec at 0.1% polymer content; 0.05 cm/sec at 0.25%, average rate 0.13 and 0.18 cm/sec). Vapor bubbles are then formed under the surface along with a growing foam layer, a sudden ejection of the surface layer into the flame zone, where a quick combustion takes place as a combustion of suspended individual drops. After combustion of this suspension (a flashing in case of a large polymer content) the cycle is repeated. Poorly thickened MN products pulsate with relatively constant frequency and amplitude. With a 0.25% polymer solution the average rate (cm/sec) grows linearly with pressure (kg/cm²) between 1 - 1.5 kg/cm² (first combustion type): $w = -0.049 + 0.168p$ (1). With $p > 2.6$ kg/cm² in $w = f(p)$ (2), (1) is overlapped by a pulsation of another kind (second combustion type). This causes an abrupt rise of the mean combustion rate. With pure MN the 2nd type begins at ~ 1.7 kg/cm². In addition, the 1st type is suppressed with a rise of the initial pressure. A rise of viscosity raises the minimum pressure at which the second type begins. Thus, an MN solution containing 5% of the polymer burns nonuniformly at 1 - 3 kg/cm² (1st type, while burning uniformly without pulsating at 3 to 9 - 10 kg/cm², and with pulsation at > 10 kg/cm² (2nd type). Ethyl nitrate (EN) is 16 times slower in burning (~ 0.07 cm/sec in a 15-mm

Card 2/5

B110/B101

glass tube). Small vapor bubbles rarely break through the smooth surface. With 0.05% PMMA it undergoes a pulsating combustion with a weak amplitude. The surface of the boiling liquid is not smooth, and bubbles distort it continuously as they break through. The rate of combustion drops as a function of the degree of burning out. In case of a polymer content over 0.5%, combustion becomes more uniform, while its main rate drops. At a polymer content \gg 2%, combustion is interrupted. Similar conditions prevail in the binary explosive, 60 wt% diglycol dinitrate in tetrannitromethane, at a combustion rate of 0.09 cm/sec. In case of a 0.25 - 0.5% PMMA content a pulsating combustion takes place, while the mean rate is lower. With a rise of the PMMA content pulsation turns weaker, and stops altogether at \sim 1.5%. Then, a uniform combustion with gradually decreasing rate takes place. Methyl methacrylate monomer effects a rise of the rate, but no pulsation. K. K. Andreyev et al. (Ref. 2: Termicheskoye razlozheniye i goreniye vzyryvchikov vysokomastv. Gosenergoizdat, M.-L. 1957, str. 130) showed that thickened liquid nitro-ester (nitrocellulose) stabilizes combustion, and that gelatinized explosives burn uniformly, just like binary mixtures of nitric acid with liquid fuels, that have been gelatinized by means of PMMA. The pulsation

Card 3/5

26547

S/076/61/035/C01/011/016
B11C/E101

Pulsating combustion of...

described here is, however, brought about by evaporation of the liquid explosive in the heated layer of the condensed phase. PLEMA is less volatile, and, under the conditions of combustion, is not capable of gas formation. Fractional evaporation and impoverishment of the heated zone at the explosive take place. It becomes more viscous, forms a film, and prevents the vapor from escaping. The higher viscosity renders the diffusion balancing with the residual liquid more difficult. The rate drops as the layer thickness grows. If the vapor pressure of the foam bubbles becomes high enough, vapor is expelled along with liquid particles dragged along, and the cycle is repeated. On a rise of pressure the 1st type is probably suppressed by 1) drop of viscosity; 2) drop of amplitude and rise of frequency due to an increase of burning rate; 3) decrease of layer thickness. On a rise of pressure, a surface disturbance causing a pulsation may arise according to L. D. Landau's mechanism (Zh. eksperim. i teor. fiz., 14, 240, 1944). The lower pressure limit of the transition to the 2nd type rises with viscosity. At a relatively high burning rate (MN), the 1st type prevails. In case of a very slow combustion, a change of the composition of a thick layer may gradually take place with an amplitude drop due to convection, diffusion, and

Card 4/5

Pulsating combustion of...

26547
S/076/61/C35/004/C11/016
B110/B101

gravitational flows. Thus, a gradual polymer concentration of a growing layer and a dropping burning rate are observed in EN until extinction due to heat losses in a tube with small diameter. The uniformity of combustion of nitroesters thickened by means of polymers is probably disturbed. There are 1 figure, 2 tables, and 5 references; 3 Soviet-bloc and 1 non-Soviet-bloc. TITLE: Some peculiarities of the initiation of detonation in low-density explosives.

PERIODICAL: Akademika nauk SSSR. Doklady, v. 141, no. 2, 1962, 359-361

TEXT: I. F. Blinov's and one of the present authors' observation that aromatic dinitro compounds of low density (below 1.0 g/cm³, the specific gravity) do not detonate any more in wire tubes has been investigated more closely. Experiments were made with nitroxylin (T216-6 N) in tubes

10-10.5 and 21-30 mm in diameter. Lead azide, density 2 g/cm³, in glass tubes of different diameters was used as initiator. By changing this diameter, the range of initial pulses, defined as explosion center, was varied. Further experiments were made with tetryl and with a mixture of ✓
4% nitroglycerin and 96% ammonium nitrate (NA mixture). In all experiments, a minimum density was found (nitroxylin 1.6 g/cm³, tetryl ~0.30-0.35 g/cm³, NA 2.0-2.1 g/cm³) at which the initiation with lead azide

Some peculiarities of the initiation...

(4 mm diameter) in wide tubes with initial air pressure in detonation. This is attributed to the fact that in the case of a narrow tube, the explosive is so quickly hurled from the center of initiation that ignition does not occur any more. In narrow tubes the propagation of the shock wave, owing to reflection from the tube walls, creates high enough to cause detonation. Ya. I. Leytman, Yu. S. Krasikov, and A. T. Belyaev are mentioned. TITLE: 31. Combustion of self-igniting explosive mixture and its transition into detonation

SOURCE: Teoriya vzryvchayushchikh veshchestv, sbornik statey, 1963,
468-474

TOPIC TAGS: explosive , detonation, self-igniting explosive , tetra-nitromethane

ABSTRACT: The conditions necessary for the detonation of tetranitro-methane-amine mixtures were studied. Numerous runs with tetranitro-methane 80.5-aniline 19.5 wt.% indicated the height of the liquid column and not its volume to be the critical condition of the transition from combustion to detonation of the self-igniting explosive mixture. There was no regularity to the time between ignition and detonation - sometimes detonation was practically instantaneous, at other times there was a several second lag. Sensitivity was increased

Card 1/2

L.17943-63

ACCESSION NR: AT3006095

with pressure increase, burning time was shortened and transition to detonation was facilitated. Mixtures of tetrinitromethane and triethylamine were studied; with o-toluidene critical conditions were quite similar to aniline. With 11.5-37wt.% xylenes there was only combustion when liquid column height was less than 3 cm; with higher columns there was regular transition to detonation. Orig. art. has: 2 tables.

TITLE: Self-ignition liquid explosive mixtures

SOURCE: Teoriya vzryvovchatykh veshchestv, sbornik statey, 1963,
499-515

TOPIC TAGS: explosive , self-ignition, liquid explosive mixture,
tetrinitromethane, explosive mechanism , nitric acid.

ABSTRACT: The spontaneous ignition of compact liquid charges (tetra-nitromethane with organic amines or other organic fuels; liquid mixtures based on concentrated nitric acid) was studied to work out application problems and to broaden knowledge of explosive mechanisms. Two methods were observed. In one, conversion of the condensed phase to reactive gases proceeds without significant temperature increase. When concentration of gases exceeds a limit, they react and detonate, but vapors of the original material do not play a significant role in the detonation. In the other type of spontan-

Card 1/2

L-17940-63

ACCESSION NR: AT3006098

4
eous ignition, an exothermic reaction occurs in the condensed phase resulting in chemical and thermal self-acceleration of the reactions. Maximum temperature is limited by boiling point of original explosive material or of its first-stage conversion products. Heat explosion and ignition occur as in previous method, only vapors of the original explosive material take part in the detonation. "Substantial part of the experiments were carried out in the All-Union scientific research institute for drilling by S. A. Lovlya, N. I. Kozlov, G. V. TITLE: Channel effect in the detonation of explosives

SOURCE: AN SSSR. Doklady*, v. 156, no. 4, 1965, 905-908

TOPIC TAGS: detonation, explosive, channel effect, shock wave, luminosity, shock wave propagation, trotyl, hexogen, lead nitrate

ABSTRACT: High-speed photography (500,000—1,000,000 frames per sec) and x-rays were used to study the channel effect in the detonation of explosives. The experiments were carried out in organic glass shells using fine ground trotyl and hexogen charges with densities of 0.5 g/cc and fine ground mixtures of trotyl and lead nitrate (10—20%) with densities of 0.6—0.7 g/cc. Analysis of the experimental data and published data showed that in all cases the boundary of the expanding detonation products is sharply delineated and never overtakes the detonation front. The luminosity observed in the channel is not connected with the motion of the detonation products. Special experiments showed that the luminosity depends on the type of gas in the channel. Maximum luminosity

PURPOSE: This textbook is for students of the special course "Economics and Organization of the Metal Industry" at Institutes of Higher Education. In addition, it may be useful to workers in scientific research and planning institutes, and also to personnel working in the nonferrous metal industry.

COVERAGE: The book discusses the role of the nonferrous metal industry as one of the most important branches of Soviet national economy, its interrelations with other branches of industry, the basic laws of its development, its patterns of consumption, and the fields of application of various nonferrous metals. Also discussed are the basic tendencies of development of nonferrous metallurgy in capitalistic countries and in peoples' democracies. The book

(Moscow)

TITLE: Thorium and Its Compounds (Thorium i yego soyedineniya)

PERIODICAL: Uspekhi khimii, 1959, Vol 26, Nr 4, pp 408-435 (USSR)

ABSTRACT: In this paper the authors report on the discovery of thorium and characterize the element and its compounds. Until recently thorium was considered as belonging to the IV sub-group of the periodic system but at present it is placed to the actinide. So far there are no definite proofs as to the electron configuration of the thorium atom. In principle, the electron distribution of thorium may be considered as being within the limits of the Radon configuration: $6d^27s^2$ or $5f6d7s^2$ (Refs 14 to 16). Still, it has not been found out so far with which element of the actinide series the first 5f electron appears (Refs 10, 12, 17, 18). This fact and some others at the moment do not prove the presumption that the second series of the transition elements exactly begins with thorium (Refs 3, 19, 20). In spite of the fact that metallic thorium was for the first time obtained as long as 100 years ago

Card 1/4

Thorium and Its Compounds

SOV/74-28-4-3/6

industrial production of the pure metal was not feasible until 1939. In principle, the technology of thorium production consists of several stages - decomposition of monazite and dissolution of thorium, preparation of pure thorium compounds and their reduction up to metal. Thorium is a silver-colored metal gradually becoming darker in air. Metallic thorium is pyrophorous and is therefore kept under a petroleum layer. The specific weight depends on the ThO_2 -content. The highest specific weight of the pure metal ranges within the limits between $11.15 - 11.7 \text{ g/cm}^3$. Different values are given for its melting point, probably because of a varying ThO_2 -content. It is most probable that the melting point of the pure metal is in the range between $1650-1800^\circ$ (Ref 55). For the boiling point values between 3000 and 5200° were found. Its evaporation heat is 145 and 177 large caloric/mol. The heat conductivity is 0.32 watt. $\text{cm}^{-1} \cdot \text{degree}^{-1}$ at 100° and $0.35 \text{ watt.cm}^{-1} \cdot \text{degree}^{-1}$ at 300° . In heating in air the chip of metallic thorium turns up and

Card 2/4

Thorium and Its Compounds

SO7/74-28-4-3/5

forms thorium dioxide ThO_2 . Metallic thorium reacts energetically with hydrogen, nitrogen, halides, sulphur, silicon, aluminum, and other elements at considerably high temperatures. It dissolves quickly in 6-12 N hydrochloric acid and forms thorium chloride. A part of the substance, however, remains undissolved. The investigation of the structure of this residue has shown that it has a cubic structure similar to the structure of oxides and mononitrides. A complete dissolution of the metal is obtained if it is treated with hydrochloric acid containing traces of fluoride or fluosilicate. Thorium forms a great number of hydrates because it has a high charge (4+) and a comparatively small length of the ionic radius (0.99 Å). It also has a strong trend towards the formation of complex compounds with the anions of various salts: nitrates, sulphates, sulphites, carbonates, fluorides, iodates, bromates, chlorides and chlorates, oxalates, tartrates, citrates, etc. Moreover, it forms complexes with diketones of the type of acetyl acetone. Numerous complex compounds were extracted by various solvents. The maximum value of the coordination

Card 3/4

Thorium and Its Compounds

SC7/74-28-4-3/6

number of thorium in aqueous solution obviously equals 8. Thorium is of great importance in the production of refractory alloys. It easily forms alloys with aluminum, iron, copper, cobalt, nickel, gold, silver, boron, platinum, molybdenum, tungsten, tantalum, zinc, bismuth, lead, mercury, scandium, beryllium, silicon, and selenium. Thorium does not form amalgam with mercury because its solubility in mercury is very low and amounts to only 0.0154 %. Thorium was used very much in the industry in the years 1880 to 1890 when it was used in the production of incandescent gas lamps. After electricity had been introduced in economy it was scarcely noticed for a considerable amount of time and did not gain its practical importance until 1940, above all in the field of investigations of nuclear energy. In conclusion, this paper gives the synthesis methods of thorium compounds and their characteristics. Table 1 - radioactive series of thorium, table 2 - radioactive properties of the thorium isotopes, table 3 - interaction of thorium with organic acids. There are 3 tables and 311 references, 28 of which are Soviet.

Investigation of the sorptive and catalytic properties of active manganese dioxide with respect to vapors and gases
E. V. Akhreevskii and Z. B. Gofman - *J. Russ. Chem. U.S.S.R.*, 4, No. 4, 1934. According to the nature of the adsorbent there can take place adsorptive, chemisorptive and contact-catalytic processes during sorption in the case of the active MnO₂. The static adsorptive activity of MnO₂ with the vapors of some org. compounds was tested, and the increase of adsorption with the increase of mol. wt. of the homologs was shown. The isotherms of adsorption of CCl₄ and CHCl₃ were investigated. These were characterized by sharp curves showing the beginning capillary condensation. The chemisorptive character of the behavior of aniline toward MnO₂ accompanied by the oxidation of aniline to azobenzene was ascertained. The dynamic activity of granulated MnO₂ to the vapors of aniline was tested and the chemisorptive character of benzonitrile vapors was shown with respect to active MnO₂, which at the same time effected a hydration of the benzonitrile to benzamide. The adsorption of NH₃ by the active MnO₂, at 0°, 50°, 100° and 200°, was also investigated. V. D. Karsenko

AVAILABILITY METALLURGICAL LITERATURE CLASSIFICATION

THE ANALYTICAL CHEMISTRY OF ORGANIC NITRO COMPOUNDS
I. Determination of nitrogen in nitro compounds by
means of alkali fusion. I. V. Alekseevskii and Z. P.
Gol'dfarbkh. *J. Applied Chem. (U.S.S.R.)*, 9, 1415-41
(in German 1942) (1961). - Nitro compds. are fused with

KOH or NaOH in an iron tube, and the NH₃ evolved is absorbed in 0.08 N H₂SO₄. For some mononitro compds., particularly mononitrophenols, the use of Zn powder or Al is not necessary, but for dinitro or trinitro compds. the results will be low unless one of these is added. The method is not applicable to liquid and easily volatile nitro compds. For *n*-O₂NCH₂OH the reaction is O₂NCH₂OH + 4H₂O = 1.5C + 3.5CO₂ + 3H₂ + CH₄ + NH₃. At a certain temp. interval the reaction of the H formation may predominate over that of CH₄. O₂NCH₂OH + 5H₂O = 1.5C + 4CO + 5H₂ + 0.5CH₄ + NH₃. Addn. of certain C compds. increases the reducing power of alkali because of an increase of the amt. of active C, which, upon reaction with water, produces the necessary excess of H. Thus, the addn. of sugar or starch produces an effect almost equal to that of Zn powder, but the addn. of certain org. acids and phenols gives neg. results. Twenty references.

PROCESSES AND PROPERTIES 603

The properties of copper glycolates. A. A. Grinberg and Z. E. Gol'danskii, *J. Gen. Chem. (U.S.S.R.)* 11, 1030-43 (1941).— $(\text{NH}_3\text{CH}_2\text{CO}_2)_2\text{Cu}$ exists as needles (I) and blue platelets (II). Both are monohydrates, but II loses H_2O at 108° whereas I must be heated to 130° and then partly decomposes. The H_2O solv. of I at 25° is 0.381 g. per 100 g. soln. and at 0° 0.303 g. The corresponding solubilities of II are 0.621 and 0.181. When mixts. of I or mixts. of I and II are allowed to stand, the solv. falls to that of II. Rise in temp., stirring, and the presence of II hasten this change. No difference between I and II is found in cond. or chem. reactions. The compds. are probably geometrical isomers, and by analogy with the Pt and Pd analogs, the more stable II should be the trans form.

GOL'BRAYKH, Z.Ye.

The simultaneous precipitation of copper in the determination of platinum and palladium. Z. E. Gol'braykh (Leningrad Inst. of Tech.). *J. Appl. Chem. U.S.S.R.* 25, 1311-13 (1952) (Engl. translation); *Zhur. Priklad. Khim.* 25, 1249-65.—In the optn. of Pt by HCO_3H , in the presence of Cu^{2+} , the quantity of enptd. Cu is independent of the Cu^{2+} concn. in the soln. This quantity constitutes 27-9% of the Pt wt. in the case of reduction of $[\text{PtCl}_4]^{2-}$ and 20-2% of the Pt wt. with reduction of $[\text{PtCl}_4]^{2-}$. If the Cu^{2+} content of the soln. is decreased considerably below that in the stoichiometric ratio Pt:Cu = 1:1, practically all of the Cu is tied up by the Pt. In the detn. of Pd by reduction of $[\text{PdCl}_4]^{2-}$ in the presence of Cu^{2+} , there is practically no copptn. of Cu by the Pd. The extent of simultaneous pptn. of Cu under conditions of joint pptn. of Pt and Pd depends upon the ratio between pptg. metals. With ratio Pd:Pt = 4:1 the tie-up of Cu does not exceed 1% of the total wt. of metals. In the analysis of sludge which is relatively rich in Pd, the total metals (Pt + Pd) can be detd. with acceptable accuracy by HCO_3H .

Position of the Detachable Door Bar (Blokirovka khoda
koksovytakkivatelya s polozeniem dveres"yemnoy shtangi)

PERIODICAL: Koks i Khimiya, 1959, Nr 6, pp. 25-26 (USSR)

ABSTRACT: The danger to workmen involved by the operation of a coke ejector can be avoided by adopting the system suggested by the author, the scheme of which is shown in the figure, p 26. The terminal contact breaker 4KN-2, which enables movement of the coke ejector to its original position, is disconnected from the by-pass button K0 and the terminal contact breaker T3 becomes connected in parallel but its contacts short-circuit as the bar goes into the furnace. When the door is removed, the path of the coke ejector through the contacts of the terminal contact breaker 4KN-2 will be possible only when the bar returns to its initial position. Further precautions are mentioned. There is 1 figure.

TITLE: The Influence of Viscosity of the Selection of the Working Fluid of Hydraulic Transmissions ("Vliyanie vysokosti na vyber rabochey zhidkosti pri operezatsii")

PUBLICATION: Avtomobil'naya promst., 1984, No. 1, p. 25-30 - USSR.

ABSTRACT: The Moscow Automobile Plant imeni Likhachev is working on the development of a hydraulic transmission for the town bus "BIL-129". One of the design peculiarities is that the oil serves as a lubricant besides serving as a working fluid in the torque converter. The design requires a special oil with low viscosity and a maximum specific weight. A suitable design of the torque converter may change the requirements for the working fluid. Detailed investigations were conducted to select a working fluid for the torque converter "BIL-129". This working fluid considerably improved the work characteristic of the torque converter. Figure 1 shows the characteristics of the "BIL-129" torque converter. The research was divided into test stand operations and actual road tests. The latter were performed over a distance of 75,000 km with a "BIL-129" bus with a load corresponding to 75 passengers. For these tests oils of types "ITM" and "MTM-2" were used

Card 1/2

UV-117-18-10-7/16
The Influence of Viscosity of the Selection of the Working Fluid of Hyddraulic Transmissions

No excessive wear was detected. The characteristics of the oils "ITM" and "ITM-1" are shown graphically. It was established that a three-stage torque converter is sensitive to the viscosity of the working fluid. Its sensitivity increases with decreasing viscosity. For the future, synthetic working fluids which possess the required properties of a working fluid and are lubricants at the same time may become important. There are 6 graphs.

SCV/175-58-6-31/41

AUTHOR: Golchin, Yu.

TITLE: Ejection

PERIODICAL: Tankist, 1958, Nr 6, pp 48-50 (USSR)

ABSTRACT: The author draws attention to a device mounted on the tank barrel. It is not a muzzle brake, nor a flame extinguisher but an ejection device. The principle of this device is based upon the utilization of the kinetic energy of a fluid medium for the purpose of pressing out another fluid medium. It may be gas, a liquid, vapors, etc. The principle of the ejector is shown in a sectional drawing (Figure 1). The high-pressure gas enters the sphere of a low pressure gas. The velocity of the first increases, pressure drops and rarefaction follows. This causes suction of the low-pressure gas into the flush chamber. The stream of the high pressure gas seizes the low pressure gas and enters a diffuser. The velocity of the gas mixture decreases,

Card 1/3

REV/175-58-6-31/41

Ejection

the pressure rises and causes the final exhaustion. The ejection principle is widely applied in the cooling of engines. The ejection system is utilized in cooling the type DMT-250 Diesel electric tractor ("Tankist" Nr 8, 1957). Ejecting mufflers are installed on small tonnage vessels provided with Diesel engines. (V.A. Baloborodov, "Contemporary Diesels on Small Tonnage Vessels" 1941). A sectional drawing shows the flow of the gases (Figure 2). Powder gases saturated with carbon monoxide, entering the fighting compartment of the tank are harmful to the human organism. For blowing through the gun bore, the ejection device is employed. On the barrel of the gun, near the muzzle, a special jacket is mounted. A sectional drawing shows the arrangement (Figure 3). In the barrel walls, several holes are bored at an angle of 20° - 30° with the bore axis. These holes are provided with nozzles. On firing,

Card 2/3

SCV/175-58-6-31/41

Ejection

prior to the projectile leaving the gun, the powder gases enter the jacket. The pressure in the jacket attains 20 to 30 atmospheres. After the shell has left the gun bore, the gases escape from the jacket towards the muzzle with great velocity, creating behind them a sphere of low pressure. The gases remaining in the bore and in the cartridge case follow the gases flowing from the jacket and escape through the muzzle. This arrangement reduces the concentration of carbon monoxide in the fighting compartment of the tank by 8 to 10 times. This means the creation of normal working conditions for the tank crew. There are 3 sectional diagrams.

Orig Pub : Gaz. wied. techn. sanit., 1956, 30, No 5, 227-227.

Abstract : A brief description is given for the methods of preparing synthetic gas from the degassing of a coal-like solid fuel. A description is given of the Coppers-Tetzek Method, which is based on the degasification of coal dust with oxygen. Data is supplied on the plants which are manufacturing synthetic gas by this method.

Title : Chemiluminescent Indicators For Neutralization Reactions

Orig Pub: Chemic, 1953, 11, No 12, 402

Abstract: Described is the application of 2, 4, 5-triphenylimidazol (lupin) (I) as chemiluminescent acid-base indicator. For every 100 ml of the titrated solution, 5 ml of a 3% H₂O₂ solution, 1 ml of a 5% K₃Fe(CN)₆ solution, 1 ml of 0.45% ethanol solution of I, 30 ml of 96% ethanol are added in the dark and titrated with

NaOH solution. At the titration end point (pH of 8.9-9.4) the whole solution becomes luminescent that lasts > 1 minute. Accuracy of the titration with I corresponds to that attained in titrations with phenolphthalein. I is particularly useful in the titration of colored solutions. -- A. Nemcruk

Choice of the coke-oven type. Stanislaw Golczewski.
Hutnik 18, 481-4(1951).—G gives a short characteristic of various coke ovens. The following items are discussed: type of charge, width, length, and height of coking chambers, efficiency of the oven, and type of fuel. Vertical and horizontal cross sections of the ovens, the convergence of solewalls, refractory materials used in construction of the oven and heat regenerators, and methods of collection of gaseous products are described. Adam J. Pitsch

Golezowski S. Classification of Coke Ovens.
"Klasyfikacja pieców koksowarzywowych". Wydruk. Nr. 3, 1935, pp.

165-170, 3 figs., 4 tabs.

Definition of a coke oven. Fundamental classification of coke ovens:
1) directly heated ovens differentiated as to open ovens and closed
ovens; 2) indirectly heated (by products) ovens, differentiated as to
muffle ovens and chamber ovens. Chamber ovens are subdivided into
vertical chamber and horizontal chamber ovens with a further differen-

1002.01.0

c

itation between ovens with horizontal heating flues and ovens with vertical heating flues. Next, the author characterizes and classifies exclusively horizontal chamber ovens with vertical flues and distinguishes: 1) ground based ovens and floor ovens — differentiated according to the type of the oven bed; 2) waste heat, recuperative and regenerative ovens — differentiated according to the method of utilizing waste heat; 3) ovens of down draft, up draft and reversible flow direction — differentiated according to the direction of combustion in heating walls; 4) ovens with the total wall surface heated, ovens with half wall surface heated and ovens with centre heated walls — differentiated according to the system of heating the coking chambers; and 5) ovens of vertical and hairpin system of flues. Types of regenerators; double-divided ovens and individual regenerators. Methods of oven firing: by means of one kind of fuel gas — single fuel oven; by means of two kinds of fuel gas — dual fuel oven. Detailed classification table of horizontal coking chamber ovens with vertical heating flues including trade names and description of outstanding features of design and construction of elements.
