Abstract: Experiments were conducted in 1947-1955 at the
Experimental Station of Fruit Growing AS Georgian
SSR in an apple orchard, planted with biennials
in 1947, on a plot with light-clayey, brown soil.
The influence on the growth and harvest of the
young fruit trees of cultivated crops, legumes,
black fallow, mixtures of perennial grasses and

planting of annual grasses was studied. Eleven variants were established. In connection with the lack of precipitation in the conditions of eastern Georgia (Gori Rayon), experiments with perennial grasses were established with mulches and without mulches. Each variant had 3 repetitions in 24 trees. Considered were the growth of branches and thickness of trunk, leaf surface, general dimension of the tree, harvest and its quality, chemical composition and durability of fruit, development of root system, content in soil of moisture and nitrates, structure and aggregate composition of soil. Average annual growth of branches on plots with perennial grasses was twice less than in variants with legumes, black

fallow and cultivated crops. Vetch occupied an intermediate position. The depressing influence of perennial grasses on the apple tree in the first 3 years after planting was so strong that the use of black fallow and cultivated crops in the first 3 years after cultivation of grasses did not improve the condition of trees, and it began to improve only in the fourth year. With overlapping sowing of perennial grasses, their negative influence was softened. Growth of the trunk was analogous to growth of the sprouts. In the variant filled with turf, earlier leaf fall was noted even with irrigation. Mulching of the area around the trees with straw increased growth. Average weight of a single fruit of the

TITLE: Hypersound and slow neutron scattering in liquids

SOURCE: Akusticheskiy zhurnal, v. 9, no. 4, 1963, 427-433

TOPIC TAGS: hypersound neutron wave diffraction, liquid hypersound neutron wave diffraction, high frequency hypersound, hypersound neutron scattering, slow neutron scattering, hypersound slow neutron scattering, hypersound neutron scattering spectrum, hypersonic radiation, neutron scattering, neutron, scattering, hypersound

ABSTRACT: The conditions leading to neutron wave diffraction on hypersounds in liquids are analyzed, and conditions for building an experimental apparatus specified. Slow neutron scattering is found to be the most suitable because of the requirements of very high frequencies for the determination of hypersounds in fluids. The expression for the neutron energy E and momentum p during and after the scattering is represented by

$$E - E_0 = \pm u(\Omega) |p - p_0|,$$

Card 1/8

ACCESSION NR: AP4000011

where $u(\vec{r})$ can be calculated by experimentally determining p or E . For small scattering angles θ and small values of $\Delta E/2mu^2$ this expression is written in the form

$$\Delta E \approx \pm \frac{2E_0 \sin \theta}{\sqrt{\frac{2E_0}{mu^2} + 1}}$$

The discussed neutron diffraction characteristics are shown to have no analogies in optical theory, with auxiliary peaks in the neutron spectrum at zero angle neutron scattering. This effect may yield direct information experimentally on hypersounds in the limits of high frequencies. Orig. art. has: 30 formulas and 1 figure.

Title : Experimental Cultivation of Ethiopian Crambe in
Tomsk

Orig Pub : Uch. zap. Tomskiy gos. ped. in-t., 1956, 15, 437-451

Abstract : This is a brief review and results of work carried out in the agrosector of the Tomsk botanical garden and at the Tomsk zonal station. It was established that the soil-climatic conditions of Tomsk are appropriate for the cultivation of Ethiopian crambe. The yield of seeds was 12-50 cwt/ha. The seeds contain 30-44.5% of oil, corresponding in terms of its physico-chemical properties to the oil, obtained from crambe

APPROVED FOR RELEASE: 07/19/2001 CIA-RDP86-00513R000519820001-5"
In the basic regions of cultivation of this crop. The net weight of the seeds was normal. It increased in the case of earlier sowing periods. The vegetation period fluctuates between 81 and 115 days, depending on the period of sowing and meteorological conditions. Crambe grows slowly until the advent of the budding phase (daily increment of not more than 0.5 cm). It grows very rapidly during the periods of budding, blooming and fruit formation (increment of 1.5-4.6 cm per day). The growth slows up considerably during the ripening period. -- N. N. AUTHORS: Chekmarev, A. P., and Kachaylov, A. P.

TITLE: Determination of the resistance of steel to torsional deformation at different temperatures and deformation rates

PERIODICAL: Zavodskaya laboratoriya, v. 29, no. 2, 1963, 213 - 215

TEXT: The torsional testing of steel tubes is described, these having an external diameter 24 - 26 mm, internal diameter 17 mm and being made by turning in a lathe at 900 - 1200°C, deformation rate 14 - 253 sec⁻¹. The torque was measured with wire strain gauges. Torque, torsion angle and number of revolutions of the spindle were recorded with a Siemens galvanometer oscilloscope. The dependence $\tau = f_1(\psi)$ where $\psi = \alpha\varphi/l$, φ -torsion angle, l -length of specimen, was obtained from the torque versus torsion angle curve from the equation $\tau = M_t/2\pi a^2 h$, where τ -resistance to deformation, M_t -torque, a -radius of the specimen, h -thickness of the wall. With the aid of the relations $\tau = \sigma/\sqrt{3}$, $\psi = 2c$, $\psi = 2u$ the $\sigma = f(u)$ curves can be determined for different degrees of deformation and different tempera-

tures, σ is the resistance to deformation, ϵ is the degree of deformation, %, $\dot{\epsilon}$, u is the rate of deformation, sec^{-1} . The relation $\gamma = 2\epsilon$ is valid to $\gamma \leq 60\%$. Tests with P18 (R18) steel gave good agreement with published data among them those of P. M. Cook, A. W. McCrum (The calculation of load and torque in hot flat rolling, BISKA, March (1958)).

TITLE: Plasticity of steel at high temperatures

SOURCE: Dnepropetrovsk, Institut chernoy metallurgii. Trudy, v. 21, 1965. Prokatnoye proizvodstvo (Welding production), 306-309

TOPIC TAGS: low chromium steel, high chromium steel, plasticity, high temperature effect, torsion strength / MaKh15 low-Cr steel, Kh982 high-Cr steel

ABSTRACT: Plasticity is one of the features that must be considered when selecting the regime of heat treatment for any mark of steel; it is highly influenced by temperature. In view of the current rapid advances in the production of high-alloy steels and alloys which are prone to overheating (above the liquidus), the need for a method of quick preliminary determination of the plastic properties of steel at high temperatures has become particularly acute. The torsion test is gaining increasingly popularity in this respect. Its findings are used to plot the number of twists until rupture as a function of temperature. However, various investiga-

tors use specimens of various dimensions (particularly length) when studying plasticity by means of the torsion test, and this complicates a comparison of the experimental findings. To eliminate this complication, the authors propose using a new plasticity indicator in lieu of the number of twists until rupture (which are greatly affected by the length of the specimens), namely, the relative angle of twist until rupture:

$$\theta = \frac{\varphi}{l_w},$$

where θ is angle of twist at rupture, radians; l_w is the length of working part of the specimen, mm. This eliminates the effect of dimension of the specimen on the experimental findings. To confirm the validity of this formula, hot twist tests were carried out with the aid of a clamp revolving at the fixed rate of 150 r.p.m. The values of the plasticity indicator θ were calculated for each temperature (900, 1000, 1100 and 1200°C) with respect to 10 marks of steel. The findings, as presented in the form of curves in Fig. 1, which shows that, e.g. steel no. 2 (ShKh15 low-Cr steel) displays maximum plasticity ($\theta = 1.7$ radians) when hot-twisted at 1000°C, whereas at the same temperature the θ of steel no. 5 (Kh952 high-Cr steel) falls to its minimum (0.7 radians). Considering that octahedral displacement is a good criterion of the change in deformation on transition from one stressed state to another, and further con-

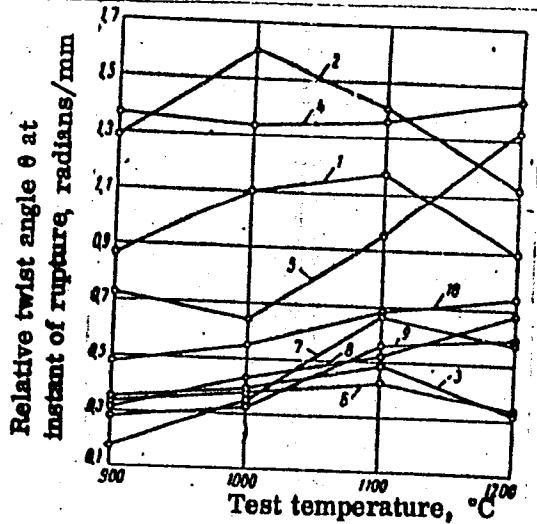

Fig. 1. Indicator of plasticity of steel during twisting as a function of test temperature. The figures on the graph pertain to the ordinal number of the steel tested.

Cord 3/4

L 41262-66

ACC NR: AT6012090

sidering that relative rolling reduction $\epsilon = h_0 - h_1 / h_0$, at which the first signs of fracture appear, serves as the criterion of the maximum plasticity of steels and alloys, the authors calculated as follows the ratios of relative displacements γ during torsion to relative reductions ϵ :

ϵ	0,1	0,2	0,3	0,4	0,5	0,6	0,7	0,8	0,9
γ	0,183	0,399	0,657	1,0	1,5	2,33	3,9	8,37	27,02

Since $\gamma = \theta R_{av}$ and the specimens tested had a 9-mm radius of working part, it is possible with the aid of the above data to refer maximum plasticity to the corresponding degree of relative reduction during rolling. These findings make it possible to compare the plasticity of metals at high temperatures so as to accordingly improve their hot working. Orig. art. has: 1 figure, 2 tables.

TITLE: Effect of work hardening and temperature on the <u>mechanical properties</u> of Kh18Ni10T steel <i>14</i>			
SOURCE: <u>Dnepropetrovsk. Institut chernoy metallurgii. Trudy, v. 21, 1965. Prokatnoye proizvodstvo (Welding production), 310-313</u>			
TOPIC TAGS: tensile testing machine, stainless steel, mechanical property, temperature dependence, material deformation / <u>UM-5A tensile testing machine</u> , Kh18Ni10T steel <i>26 4 10</i>			
ABSTRACT: This effect was investigated for specimens of <u>hot-rolled</u> Kh18Ni10T stainless steel 3.8-3.9 mm thick which were rolled in a four-high mill to various degrees of deformation (8, 13, 20, 40, 60, 70 and 75%) and then subjected to hot tensile strength tests at five different temperatures (0, 100, 200, 300 and 400°C, 20 min each time) in an UM-5A tensile testing machine in order to elucidate the influence of the temperature conditions of deformation on			
Card	1/4		

L 41263-66

ACC NR: AT6012091

the yield point. To this end, a tubular electric furnace measuring 300 mm in length and 95 mm in inside diameter was attached to the UM-5A machine. The findings were used to plot the yield point $\sigma_{0.2}$, ultimate strength σ_B and elongation per unit length δ as a function of the degree of preliminary deformation for each of the five test temperatures (Figs. 1, 2, 3)

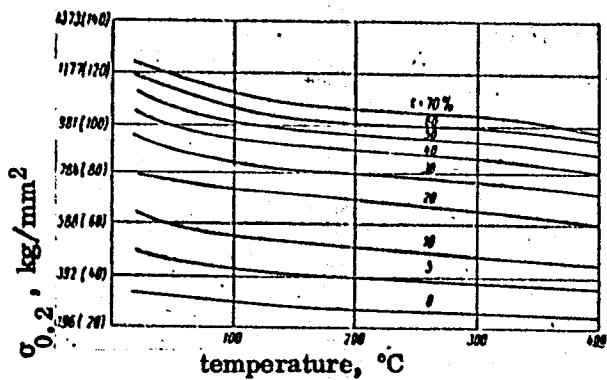

Fig. 1. Effect of temperature and degree of deformation on the yield point of Kh18Ni10T steel

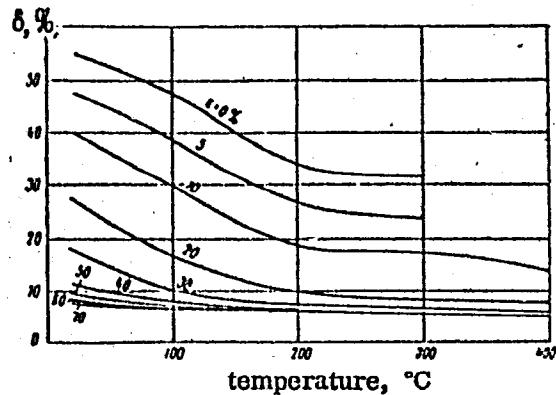

Fig. 3. Effect of temperature and degree of deformation on the elongation per unit length of Kh18Ni10T

Card 3/4

L 41263-56
ACC NR: AT6012091

It is thus established that $\sigma_{0.2}$ and σ_B decrease with increasing temperature and that for $\sigma_{0.2}$ this decrease is virtually independent of the degree ϵ of deformation. The effect of temperature is the strongest within the ranges of 20-200 and 300-400°C. As ϵ increases the strength characteristics increase for any test temperature. The plasticity of steel decreases both with increase in preliminary deformation ϵ and with increase in temperature within the limits investigated. Orig. art. has: 4 figures, 1 table.

On the whole, it is established that Kh9S2 steel displays maximum plasticity at 1200°C and hence this is the optimal temperature of heat treatment for this steel. As for the effect of strain rates, measurements of Rockwell hardness H_{RC} showed that it increases with increase in strain rate, since higher strain rates retard crystallization, and increase the crystallization temperature. TITLE: Determination of the plastic yield stress at high temperatures applying high rates of deformation

PERIODICAL: Zavodskaya laboratoriya, v. 28, no. 8, 1962, 971 - 975

TEXT: Specimens of titanium alloyed with Al, V and Mo were tested in a tensile testing machine at stretching rates of 222, 520 and 1400 mm/sec. The deformation rates were 556, 1300 and 3500 %/sec. The force acting on the samples was measured with a pressure cell and electric strain gages. During the experiment the samples were subjected to temperatures of 600, 700, 800, 900, 1000, 1100, and 1150°C inside a tubular furnace. Elongation was measured by strain gages and contraction photoelectrically. A specimen was stretched at a rate of 222 mm/sec after annealing at 1000°C for 10 min; its failure occurred after 0.9 sec and the elongation was 50%. There are 4 figures and 1 table.

TITLE: Temperature dependence of deformation during the hot rolling of a Ti-base alloy

SOURCE: Moscow. Aviationsionnyy tekhnologicheskiy institut. Trudy, no. 62, 1965.
Obrabotka davleniyem legkikh splavov (Pressure working of light alloys), 91-100

TOPIC TAGS: titanium base alloy, hot rolling, temperature dependence, plastic deformation, impact strength, metalworking, ultimate strength, elongation

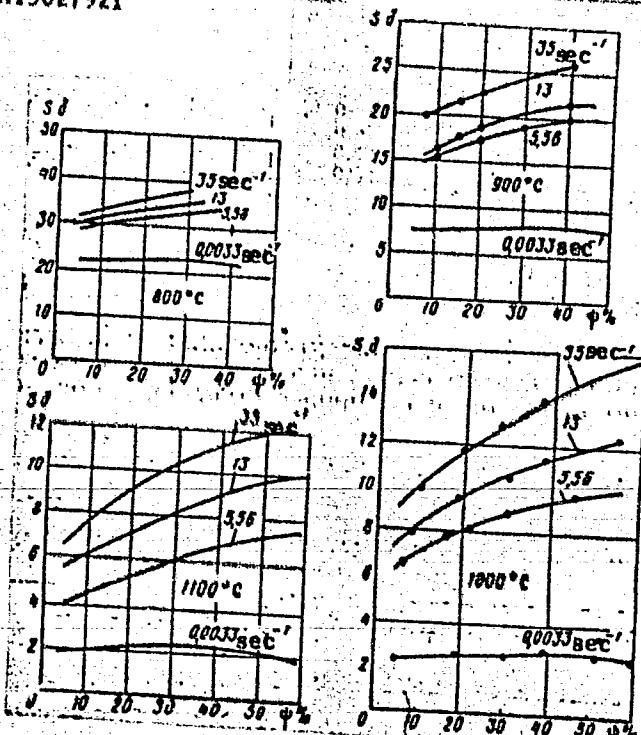

ABSTRACT: The author presents the results of an investigation of the technological properties of a Soviet-developed Ti-base alloy treated with Al, V, Mo and Zr, performed with the object of determining the optimal temperatures and strength characteristics during its hot working. This alloy has the structure of ($\alpha + \beta$)-phase. At 500°C sheets of this alloy have an ultimate strength of ~ 70 kg/mm² and relative elongation of 24-26%. Impact tests of specimens were performed as temperatures of from room temperature to 1200°C with the object of determining the maximum degree of deformation prior to the appearance of the first crack; the degree of deformation could be adjusted by mounting rings on the table of the impact testing machine with the object of

Fig. 1. Variation in deformation resistance S_d as a function strain rate and of degree of deformation at various test temperatures.

ACC NR: AT5027921

restraining the motion of the ram. These tests showed that the optimal temperature range for the hot working of this particular alloy is 800-1100°C, since then the impact strength and degree of deformation prior to appearance of first crack are maximal. Hot rolling of specimens in a two-high mill at temperatures of 800, 900, 1000 and 1100°C with degrees of deformation amounting to 10, 20, 30 and 40% in the presence of dynamometers made it possible to plot the mean unit roll pressure P_m as a function of temperature and the $t:h$ ratio (ratio of length of area of deformation to mean thickness of strip). Tensile tests of specimens made it possible to determine the variation in deformation resistance S_d as a function of the strain rate and degree of deformation at various test temperatures, on using as the tensile testing machine a 3-ton chain-type drawing mill with the traveling rate of the chain being successively adjusted to 222, 520 and 1400 mm/sec; for specimens 40 mm long the deformation rate in this case was 5.56, 13 and 35 sec⁻¹, respectively (Fig. 1). Analysis of the experimental findings by means of Tsalikov's formula (Prokatnoye proizvodstvo. Handbook, edited by Ye. S. Rokotyan, vol. 1; Metallurgizdat, 1962) showed that the attendant friction coefficients are quite acceptable in practical engineering calculations.

"O zastosowaniu niektórych soli kwasu trójtioglowego w analizie jakościowej kationów". Przemyśl Chemiczny, No. 8, 1935, pp. 317-320.

A simple method has been devised for obtaining an approximately 1% aqueous solution of sodium tri-thio-carbonate by treating NaOH solutions with hydrogen sulphide and carbon disulphide. This solution, diluted 1:10, almost odourless and of prolonged stability, was used instead of hydrogen sulphide as a group reagent for precipitating sulphides of the second and third cation groups.
