Abstract : The dangers of work with open sources of ionizing radiation are investigated. The permissible limits of external and internal exposure to radioactive substances are reduced. A classification of radiochemical laboratories by intensity of exposure is cited. Radioactive isotopes used in the role of indicators are divided into groups by relative danger, with a calculation of the character of their emission, half-life, as well as a specification of the absorption by the organism of corresponding isotopes

Card 1/2

and the separation of these from the organism. Radiochemical laboratories for indicators and low levels of activity are briefly described. Methods of coping with radioactive pollution both in the laboratory and in the area around it are investigated.

TITLE:

Separation of different oxidation states of plutonium
by the reversed-phase partition chromatography

PERIODICAL:

Nukleonika, v. 5, no. 10, 1960, 671-676

TEXT: Chromatographic separation of colloidal Pu, Pu^{III}, Pu^{IV} and

Pu^{VI} was investigated to overcome the inherent disadvantages of the spectrophotometric and radiometric methods of determining the proportions of Pu in the various states of oxidation. Tri-butyl phosphate (TBP) on kieselguhr and aq. HNO₃ were used as the stationary and the mobile phases respectively. The columns were 3 mm in diameter and 11 cm long and contained 0.30 g kieselguhr pretreated with Cl₂SiMe₂ and 0.18 ml of TBP. The stock solution was prepared by dissolving metallic Pu in HCl. To prepare Pu^{III}, a portion of the stock solution was reduced with hydroxy-

amine hydrochloride, $\text{Pu}(\text{OH})_3$ was precipitated with NH_3 and dissolved in 0.8 M HNO_3 /0.05 M hydroxylamine perchlorate to give a 10^{-5} - 10^{-4} M solution. To prepare Pu^{IV} , $\text{Pu}(\text{OH})_3$ was dissolved in 7 M HNO_3 , oxidized with warm H_2O_2 and diluted to the same concentration as the Pu^{III} solution above. To prepare 10^{-4} - 10^{-5} M Pu^{VI} in 0.8 M HNO_3 , Pu^{IV} was oxidized with Na bismuthate and colloidal Pu was obtained by the eq. hydrolysis of Pu^{IV} in HNO_3 . A mixture of the various oxidation states was made up by the partial oxidation of Pu^{IV} with diluted HNO_3 and the addition of Pu^{III} . Colloidal Pu was always present in this solution. Separation was carried out on 0.02 - 0.04 ml volumes, eluting them with 0.3 - 2.13 M HNO_3 at the rate of 4 drops/min. \leftarrow - Activity of every 5th drop was measured with a scintillation counter. Colloidal Pu and Pu^{III} are only slightly extracted from HNO_3 by TBP in sharp contrast to Card 2/4

Pu^{IV}. Position of the Pu maximum in free volumes is given by the relationship $V_{\max} = 9.62 M - 1.62$, (where M is the molarity of HNO₃), and the corresponding equation for Pu^{VI} is: $V_{\max} = 1.76 M - 0.029$. Pu^{VI} is absorbed by TBP to a greater extent than Pu^{III}, but less than Pu^{IV}. Very clean separations of Pu^{III}, Pu^{IV} and Pu^{VI} and also of colloidal Pu from Pu^{IV} and Pu^{VI} were obtained, especially when the HNO₃ was 0.5 - 1.0 M. Colloidal Pu could not be separated from Pu^{III} by this method. Complete separations required $\frac{1}{2}$ - 1½ hours. Small amounts of Pu may be separated from U by eluting a solution of UO₂(NO₃)₂, (containing Pu), with 3 M HNO₃/0.05 M hydroxylamine perchlorate, even when the $\frac{Pu}{U}$ ratio is below 10⁻⁸. The authors express their thanks to Miss K. Czaplicka for technical assistance. There are 2 figures and 3 references: 1 Soviet-bloc

AUTHOR: Fidelis, Irena; Gwozdz, Rajmund; Siekierski, Slawomir

TITLE: Separation of carrier-free sup 199 Au from platinum by reversed-phase partition chromatography

SOURCE: Nukleonika, v. 8, no. 5, 1963, 327-331

TOPIC TAGS: Au, Pt, chromatography, partition chromatography, reversed-phase partition chromatography, tributylphosphate EWA reactor, HCl

ABSTRACT: Authors applied reversed-phase partition chromatography method with tributylphosphate (TBP) as stationary phase to separate carrier-free gold from a platinum target. Radioactive Pt¹⁹⁹ and Au¹⁹⁹ tracers were obtained by irradiating spectrochemically-pure metals in the EWA reactor in a flux of 10¹¹ newtons/cm²/sec. Static coefficients of gold distribution were determined by Au¹⁹⁸ isotope. Ten ml of organic phase were agitated with 10 ml of aqueous phase with varying concentrations of HCl for 10 min. After the phases had been separated, their activity was measured with a scintillation counter. Method of preparing the columns and their operation was described previously (Siekierski, S., Fidelis, I., J. Chromatogr.,

Card 1/3

ACCESSION NR: AP3011301

4, 1960, 60; 5, 1961, 161). The static gold distribution coefficients K_{Au} were measured in the system TBP-HCl. This coefficient is very high within HCl concentration limits of 0.03 to 9 M; it exceeds 100. In the TBP-HNO₃ system, this coefficient changes its value from about 600 for 1 M HNO₃ to about 1 for 11 M HNO₃. A 0.04 ml solution of platinum in aqua regia was placed into a column. The Pt was washed with HCl of 2M, 3M, 7M and 9.8M concentrations. The platinum is washed out according to static experiments in the starting free volume. The obtained curves are sharp and symmetrical. The gold inserted into the standard column is not washed out even with 30 free volumes of HCl. The gold is not washed out with 200 free volumes of the eluate, regardless of the HCl concentration. It is washed out immediately by concentrated nitric acid. An analysis of curve plotted for platinum and gold shows that the width of the maximum for Pt depends upon the volume of the solution placed into the column. The position of this maximum is, for all intents and purposes, not subject to any changes associated with the concentration of the washing-out HCl. After the Pt is washed out, the gold is washed out immediately by concentrated HNO₃. Further, 95% of the gold's activity flowed out from the column in the form of a sharp maximum in a 5 drop volume, i.e. about 0.1 mL. This shows that the gold indicator solution was concentrated about 100 times in the column. Orig. art. has: 3 figures.

TITLE: Laboratory Investigations of Anchor-ice Diversion Tunnels on a Model of the Powerhouse Substructure of the Oktemberyan Hydroelectric Power Plant (Laboratornyye issledovaniya shugosbrosov na modeli napornogo uzla Oktemberianskoy GES)

PERIODICAL: Tr. Arm. n.-i. in-ta gidrotekhn. i melior., 1957, Vol 2,
pp 105-124

ABSTRACT: The paper examines the problem of model simulation and methods of laboratory study of anchor-ice diversion tunnels. Several types of anchor-ice substitutes were tested by experiment, of which paraffin-impregnated pumice stone, with a volumetric weight of 0.6-0.8 ton/m³ and a diameter of particles of 0.2 to 3.0 cm, was found to be the most suitable. The powerhouse substructure model of the hydroelectric power plant was built to a scale of 1 : 18 and the rate of the model discharge was ~ 11 liter/sec. Studies were made in regard to the type, dimensions, and location of a floating skimming boom in front of the forebay, the location of the anchor-ice diverter in the

Laboratory Investigations of Anchor-ice Diversion Tunnels (cont.)

forebay and the design of the anchor-ice diversion tunnels. Tests were carried out by dumping the anchor ice through a siphon spillway having an inlet opening in the shape of a horizontally flared bell-mouth, through diversion tunnels of three different types, and through a chute spillway. Suggestions for the design of anchor-ice diverters are presented.

TITLE: Spillway
The Siphon Shaft/(Sifonnyy shakhtnyy vodosbros)

PERIODICAL: Gidrotehnika i melioratsiya, 1958, Nr 9, pp 27-34 (USSR)

ABSTRACT: The installation of a siphon shaft spillway in reservoirs to ensure an efficient discharge of flood waters was first proposed by O.V. Vyazemskiy in 1946. It has been tested since then by the hydrotechnical laboratory of the Armenian NIIGIM and recommended for general use as the most efficient and economical means of keeping reservoirs from overflowing flooding adjacent regions. The construction consists of a vertical shaft with a cone-shaped lid. The water penetrates in the space between the edge of the shaft. The lid, permanently fixed at a determined height, sucks in the air from beneath the lid, creates a vacuum and the whole structure works as a siphon. Results of tests showed that the amount of superfluous water discharged in this way was 55 to 60% larger than by a conventional spillway. The shaft can be built from prefabricated tubes of reinforced

'56. The Influence of enzyme activities on the quality of bread — Enzimaktivitások befolyása a kenyér minőségre — A. Gyárfás (Food Industry — Ételfogyasztási Ipar)

— Vol. 6, 1954; No. 11, pp. 332—335, 10 figs.)

The role of amylases and proteases of various origin were investigated in the baking of bread. For the measuring of alpha-amylase activity the Kneen-Sandstedt method, for that of beta-amylase the Willstätter-Hagedorn-Jensen method and for measuring protease activity the van Slyk micro-method can be applied. Products containing alpha-amylase are prepared from wheat or barley, moulds and bacteria. In respect to the quality of bread the best results were obtained with germinated flour extracts. Alpha-amylase of bacterial (*Bacillus mesentericus*) origin is not adequate for baking bread since the soft part of the bread becomes viscid due to increased starch hydrolysis although alpha-amylase promotes the formation of gas. Experiments conducted with extracts prepared from *Aspergillus oryzae* have proved that although their alpha-amylase activity was satisfactory, their protease activity was too high for the production of good-quality bread. Experiments aimed at the appropriate inactivation of the protease of the extract were unsuccessful.

"Double Tone Reception."

Budapest, Orvosi Hetilap, Vol 104, No 30, 28 July 63, pages 1413-1415.

Abstract: [Authors' Hungarian summary] The authors stress that the Synchron double reception is extremely helpful in the indication of timing and in diagnosis. Differentiation of the tone-factors is usually done easily. The transport of murmurs is recognized with more certainty than with auscultation. The method differentiates well between systolic murmurs above the large vessels due to stenosis and systolic murmurs originating in the atrio-ventricular level due to regurgitation. This is especially useful in cases of arrhythmia. In cases of combined heart disease, the method can be used in the evaluation of the extent of the disorder in individual valves.

3 Hungarian, 4 Western references.

1/1

The usefulness of double phonocardiograms, taken by the method described by the authors Ibid., Vol 104, 1963, p 1413, was discussed on the basis of three year's experience in using the technique. It was found that the method may be of especial usefulness in recognizing the early systolic click and the diastolic noise caused by mild aorta regurgitation.

Orig Pub : Acta morphol. Acad. Sci. hung., 1957, 7, No 3, 343-350

Abstract : Three-month-old mice were inoculated intraperitoneally with 1 million of cells of an ascitic carcinoma of Ehrlich. Degenerative changes of tumor cells were studied in smears and sections taken from separate portions of ascites, obtained through tapping of mice before and after introduction of DL₅₀ preparations of methyl-bis-(β-chloroethyl)-amine at a dosage of 2 γ/g, triethylenemelamine) (TEM)

at a dosage of 5 γ/g or Hydrochloride 1.6 bis-(β-chloroethylamine)-1,6-desoxy-D-mannitol BSM) at a dosage of 100 γ/g. 22 mice were taken per dose. The studied preparations produce an increase in the volume of tumor cells, nuclei and nucleoli ~ 90%; furthermore the cells and nuclei reach maximum size after 24 hours, while the nucleoli do already after 1-3 hours. Apparently the change of nucleoli size is the finest early indicator of functional and morphologic disturbances. After 72 hours the action of the preparation clearly decreases. The preparations produced disintegration of nuclear chromatin. Under influence of TEM, chromatin dispersed and the volume of the nucleus as compared to the initial volume increased by 60% after 12 hours and twice after 24 hours. Sharp differentiations in the action of the studied preparations were not noted. -- S.A. Syrkina-Kruglyak.

1961/62
AUTHORS: Szalay, Sándor, Gyarmati, Borbala, Kovách, Ádám, Sámszoni,
Zoltán

TITLE: Meteorites as means of space exploration

PERIODICAL: Fizikai Szemle // no. 8, 1961, 227-232

TEXT: The purpose of the paper is to outline the present state of physical knowledge on meteorites. The isotope-analytical laboratory of the Nuclear Research Institute of the Hungarian Academy of Sciences, with which the authors are associated, has planned to investigate the meteorite stock of Hungarian museums in order to contribute to international research on this matter. (I) General characteristics of meteorites: In the course of the International Geophysical Year, in 1959, an estimated amount of 14 million tons of cosmic substance fell on the earth's surface. Meteorites are classed into three groups, analogous to the three principal zones building up the earth: siderites (mainly Fe-Ni alloys), siderolites (Fe-Ni alloys and silicates), and aerolites (prevalently silicates). H. Brown compiled tables on the frequency of chemical elements found in the three groups.

Card 1/3

H/016/61/000/008/001/002
B122/B227

Meteorites as means of space ...

H. C. Urey and H. Craig investigated the same on chondrules, a globular variety of the third group with a higher Fe content. (II) Isotope composition of the substance of meteorites: Elemental and isotope composition irregularities in connection with the origin of meteorites. So far, it has been found that most elements in meteorites have an isotope composition identical to that found for the same elements on the earth. This fact supports the general opinion of astronomers that meteorites originate, without exception, from the solar system. Thus, isotope irregularities can not be attributed to the particular origin of meteorites. Physico-chemical and biological fractionating effects on the substance of meteorites do not differ essentially from similar effects on terrestrial substances. External nuclear-physical effects: Meteorites have been exposed to cosmic radiation perhaps for hundreds of millions of years. Nuclear-physical emulsions exposed to cosmic radiation presented the phenomenon of nuclear cascade, the nucleons of which quit the nucleus with high energy, leaving it in a strongly excited state. When thermodynamical equilibrium has been attained, the strongly heated nucleus begins to evaporate. In the isotope composition of elements produced by such evaporation, strong differences of isotope composition are found against their terrestrial composition.
