PRELIMINARY REPORT

The dynamics of the transformation of diphtheria toxins of various types into anatoxins. T. I. Ivanova and V. N. Kalina. *Arch. sci. biol.* (U. S. S. R.) 35B, (31-40) (in French 641 2) (1934).—Toxins of varying titer and of flocculation rates produced on ordinary Martin broth with and without sugar, buffered and unbuffered, were treated with 4.5% conc. formalin 5 days. The μ curves for different types were the same. The formalinization process is accompanied by denaturation as manifested by the fall of titer and slowing of the flocculation reaction. The lowering of the titer is greater with the toxins of the higher titer and in the toxins produced on buffered media without sugar. Thermostability of the anatoxin as judged by titer develops more rapidly than that judged by the flocculation. The anatoxins from the low-titer toxins become thermostable according to titer sooner than those from high-titer toxins. Thermostability according to flocculation develops more slowly and does not coincide with the controls even 30 days. The toxins lose the larger part of their toxicity at the end of the first 5 days. Those from sugar- and buffer-contg. media are completely detoxified in 30 days of formalin treatment, while the others have a residual toxicity after 30 days. Anatoxins produced from highly antigenic toxins originating in sugar-contg. media possess great immunizing powers.

Dissociation of the hemolytic Streptococcus scarlatinae under the influence of the red streptocide. T. I. Ivancova.

Z. Microbiol., Epidemiol. Immunitätsforsch. (U. S. S. R.) 1940, No 10, 28-32 (in German, 32).—Red streptocide (sulfamylchrysoidin) in diln. of 2.5:1000 caused dissoci. of S. scarlatinae. The cultures produced gave either cloudy or slimy colonies. The original culture did not ferment glucose or lactose, left unchanged mannitol, inulin and dulcitol, but actively fermented lactose. The disord. cultures fermented both lactose and glucose; some fer- mented inulin, others mannitol, and a few did not affect mannitol and dulcitol. The colonies show lowered viru- lence as a result of dissoci. (as tested on mice). They also show low hemolytic power and decreased resistance to a phagocytosis. But they have increased resistance to a temp. of 45-60°, to a second dose of red streptocide, to 0.5%, PhOH and to 0.1% soln. of rivanol.

The nature of interaction of adenosine triphosphate with actomyosin. I. I. Ivanov and T. I. Ivanova. *Doklady Akad. Nauk S.S.S.R.* 66, 805 (1959). Actomyosin fibers treated with adenosine triphosphate (ATP) become more dense and opaque (in the course of contraction) and also become more extensible (100-200% extension is possible, with relaxation upon load removal almost to original size). Treatment of a fiber with ATP while under near-breaking tension causes increase of "density" of the fiber (with characteristic "crosshatch" surface), accompanied by loss of some water content and increase of extensibility. The extension characteristic of the fiber treated by ATP is very similar to that obtained from denaturation treatment with $CuSO_4$. The primary reaction of actomyosin gel to ATP is contraction based on syneresis of the protein gel accompanied by dehydration of the micelles. G. M. Kosolapoff

Action of high pressure on myosin and water-soluble adenosinetriphosphatase. I. I. Ivanov and T. I. Ivanova. (1st Moscow Med. Inst.). *Doklady Akad. Nauk S.S.S.R.* 77, 657-60(1951).—Evidence is collected supporting possible identity of myosin and adenosinetriphosphatase (I) (water-sol.), with 10 references. Application of 4000 atm. pressure leads to complete denaturation of myosin in 10 min. and its enzymic properties are completely lost. The water-sol. I and potato I, however, retain their enzymic properties without change under this treatment. This may lead to division of proteins into 2 groups—pressure-stable and pressure-unstable; among the latter are myosin and actomyosin. Hence the concept of myosin being a complex of myosin proper on which water-sol. I is adsorbed does not appear founded on fact. Proteins of malignant growths in contrast to myosin are stable to 4000 atm. pressure and retain their enzymic properties, which arise apparently from adsorbed cytoplasmic I.

TITLE: Deamination of d-Sarcosylsine in Normal and Tumor-Affected Tissues
(O dezaminirovanii d-sarkolizina v normal'nykh i onkologicheskikh tkanyakh)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol 122, Nr 4, pp 665-667
(USSR)

ABSTRACT: Sarcosylsine is a racemate of the p-bis-β-chloroethylamine derivative of a natural amino acid, the phenylalanine, and represents one of the most promising synthetic drugs against tumors (Ref 1). Its structural formula is given. The chemotherapeutic efficacy of preparations from chloroethylamines depends to a considerable extent upon their stability in the media of the organism. A general method for their inactivation is their hydrolysis, which is accompanied by ionization of the chlorine and by conversion into a derivative that has no toxic and therapeutic properties (Ref 2). Its mechanism of inactivation involves specific transforming processes for phenylalanine. Another method is sarcosylsine metabolism, in this typical case, the oxidation of the chloroethyl groups up to acetaldehyde and

Card 1/4

Deamination of d-Sarcosin in Normal and Tumor-Affected Tissues SOV/20-122-4-35/57

formiate (Ref 2). That part of the inactivation mechanism which concerns the transformation of the phenylalanine especially deserves particular attention since it has become known that the d-isomer of sarcosin is distinguished by a considerably reduced anti-tumor activity, as compared with the l-isomer. Both isomers exert the same effect on the bone-marrow by depressing the leucopoiesis to the same extent. Krebs (Refs 3, 4) did not succeed in supplying the experimental proof for the assumption that the reduced effect of the d-sarcosin is related with the specific deamination of d-phenylalanine by the oxydase of the d-amino acids. Therefore, the authors tried to clarify this part of the problem under review in the tissues mentioned and, in particular, in the bone-marrow. Here, another essential question could be elucidated, i.e. whether the interaction of the chloroethylamines with ferments of the tissues is connected with a necessary lesion of the ferments (Ref 4). The results in table 1 have proved an undoubted capability of the normal and tumor tissues to deaminate the d-sarcosin. The evidence, however, provides no information whether only the hydrolyzed d-sarcosin is deaminized, and

Card 2/4

Deamination of d-Sarcosyls in Normal and Tumor-Affected SOV/20-122-4-35/57
Tissues

whether the hydrolysis occurs only up to the point when the intact d-sarcosyls comes in contact with the ferment. The oxydase of the d-sarcosyls in the sarcoma 45 is distinguished by a considerable constancy of activity, whereas in other tumors (experimental and human ones) This ferment was rarely found. An understanding of the manifestations described depends upon the question whether the inconstancy of the oxydase activity is due to a real absence of the apoferment or only to the missing coferment (flavin adenine dinucleotide). This and further related questions are at present clarified by the authors. There are 3 figures and 6 references, 1 of which is Soviet.

TITLE: Solution of Laplace's equation for a Penning discharge gap

SOURCE: Zhurnal tekhnicheskoy fiziki, v. 36, no. 5, 1966, 907-912

TOPIC TAGS: Penning discharge, electrostatic field, Laplace equation, mathenatic method, approximate solution

ABSTRACT: Because of its practical significance in connection with design and study of Penning discharges, the authors calculate the electrostatic field of a charged cylinder of radius a and length $2L$ located midway between and with its axis perpendicular to two infinite parallel plane grounded electrodes separated by a distance of $2D$. The problem is first solved rigorously by separation of variables in cylindrical coordinates r, θ, z (origin of coordinates at the center of the cylindrical electrode), and a set of linear equations is derived from which the coefficients in the resulting expansion in a series of modified Bessel functions can be calculated. Because of the complexity of the calculations, a second, approximate, calculation technique is developed. This technique is based on the assumption of a particular relatively simple

Cord 1/2

UDC: 533.9

L 33399-66

ACC NR: AP6015313

form, suggested by results of electrolytic tank measurements, for the potential in the region $r = a$, $L < z < D$. The limiting cases $L \rightarrow 0$ and $L \rightarrow D$ are discussed, and numerical calculations for the case $L/D = 1/2$ are presented and compared with results of electrolytic tank measurements. The approximate calculations are least accurate near the edge of the cylindrical electrode; in this region the error is 10-20 % when 10 terms of the series are employed and the error cannot be reduced below 5-10 % even by using many more terms. The errors decrease rapidly with decreasing r , and four terms of the series give an accuracy of 1 % in the region $r < 4a/5$. The first term alone of the series gives an accuracy of 1 % on the axis. Orig. art. has: 18 formulas, 3 figures, and 1 table.

TITLE: Influence of the Heterogeneity of Welded Butt Joints On Their Deformation Under Static Load (Vliyaniye neodnorodnosti svarnykh stykovykh soyedineniy na kharakter deformirovaniya ikh pri staticheskom izgibe)

PERIODICAL: Svarochnoye Proizvodstvo, 1957, # 12, p 17-21 (USSR)

ABSTRACT: The described experimental investigation of the distribution and concentration of the elastical-plastic deformations in portions of welded butt joints under bending load was done with the purpose of determining data necessary for designing welded steel structures and for selecting the proper electrodes for such jobs. The specimens were tested on a 30-ton Amsler press. The summary small elongation deformations in the outer fibers of specimen cross sections ("fiber deformations") at various distances from the applied load were determined by an experimental method and by calculations based on the Prandtl and the Bernulli hypotheses. The measurements of the "fibrous deformations" were done with the use of electric resistance transducers (datchiki). The influence of geometrical non-uniformity of welded butt joints was also investigated. The results of the investigation are illustrated by diagrams. Doctor of Technical

PHASE I BOOK EXPLOITATION SOV/2050
 Svaraka sbornik statey, [Typ. 1 (Welding). Collection of Articles,
 Nr. 1] Leningrad, Sudpromgiz, 1958. 246 p. 4,000 copies printed.
 Ed.: O. I. Kapryin, Candidate of Technical Sciences;
 Ed.: I. A. Zhuravskaya; Tech. Ed.: K. N. Volchok.

PURPOSE: This collection of articles is intended for use in research
 institutes, institutes of higher learning, design offices, and
 plants.

COVERAGE: These technical papers deal with the results of research
 in welding technology. The main purpose of this work was to
 investigate the effects of various welding regimes and heat
 treatments on the mechanical properties of welds of austenitic
 and ferritic composition. A number of experiments also dealt
 with welding properties and weldability of austenitic
 alloys and a number of nonferrous metals. One of the main
 tasks of the research was to establish the relationship between the geometry
 of the weld seam and its physical properties. The crystallization
 of the weld, its mechanical properties, and the various factors
 affecting the grain structure of the metal were the subjects of
 scientists. Of special practical interest is the study of the
 behavior of a welded structure in which the elasticity of the
 material of the welded joint are not within the elastic range.
 These considerations lead to experiments with mechanically induced
 changes in the properties of the weld seam. Another problem which
 presents many difficulties in welding is the behavior and changes
 in the heat-affected zone next to the welded joint. One of the
 papers deals with experiments in this field. A description is
 given of the equipment and the technique used in electroslag
 welding, which is regarded as one of the major advances in modern
 welding technology. Several papers deal with special fluxes for this
 work. Most of the papers are profusely illustrated with graphs,
 diagrams, and photographs. References are given after each article.

TITLE:

Polymerization¹ of 3-Methyl Butene-1¹

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 129, Nr 4, pp 799-800
(USSR)

ABSTRACT:

The authors investigated the polymerization of 3-methyl butene-1 with a complex organometallic catalyst.¹ 3-methyl butene-1 was obtained by pyrolysis of isoamyl acetate in a yield of 97%. The dependences observed in the pyrolysis are graphically represented in figures 1 and 2. $Al(C_2H_5)_3$ or $Al(i-C_4H_9)_3$ and $TiCl_4$ or $TiCl_3$ were used as catalyst components. $Al(C_2H_5)_3$ and $Al(i-C_4H_9)_3$ were dissolved in benzene before they were used. The reaction mentioned in the title was made in carefully purified and dried heptane and in argon atmosphere. The obtained poly-3-methyl butene-1 is a white powder (melting point approximately at 240°). The properties and the polymer constants are determined. The content of the isotactic component was determined by successive extraction with boiling ether and heptane (similar to the investigation of

TITLE: On electrolytic polishing of silicon in solutions of hydrofluoric acid

SOURCE: AN UzSSR. Otdeleniye khimicheskikh nauk. Nekotoryye voprosy* khimicheskoy tekhnologii i fiziko-khimicheskogo analiza neorganicheskikh sistem (some problems in chemical technology and physical chemical analysis of inorganic systems). Tashkent, Izd-vo AN UzSSR, 1963, 256-264

TOPIC TAGS: electrolytic polishing, silicon, hydrofluoric acid, electrolytic etching, semiconductor

ABSTRACT: By means of the microstructure method, the authors have investigated the effect of prolonged polishing of silicon anodes on the change of their intermediate structure and on the quality of the obtained surfaces. By use of this method it is impossible to establish quantitative regularities; however, as opposed to other methods, it enables a more complete and convincing appearance of the polishing mechanism to be shown. The authors have conducted the experiments in polyethylene electrolytic cell located in a thermostat. A silicon sample was used as an anode, and a platinum foil as a cathode; the electrolyte was not stirred. Microscopic

Card 1/2

ACCESSION NR: AT4028541

observations and microphotographs were made with the aid of a vertical metallographic microscope of the type MIM-7. These results are shown in microphotographs. The authors drew the following conclusions: 1) the monocrystallinity of silicon leads to a substantial decrease in the speed of the electrolytic process and an increase in the quality of the polished surface obtained; 2) with an increase in the specific resistance of silicon of 20 times (from 1 to 20 ohm cm) the general pattern of the electrolytic polishing did not change fundamentally; 3) two stages are characteristic for the electrolytic process of silicon; structure etching and its polishing are obviously associated with the phenomena of anode passivation; 4) the introduction of organic additives into the electrolyte enabled the polishing time, the current density, and the stage of the structural etching to be shortened, as well as improving the quality of the surfaces obtained; and 5) as a result of the authors' research, optimum conditions were established for polishing some types of mono- and polycrystalline silicon. Orig. art. has: 3 figures containing microphotographs.

TITLE: Comparison of Methods of Introducing a Solution Into the Discharge Gap During Spectral Analysis

PERIODICAL: Tr. Sibirsk. fiz.-tekh. in-ta pri Tomskom un-te, 1958, Nr 36, pp 273-276

ABSTRACT: The authors investigated the accuracy and sensitivity of the spectral determination of Mg in solution in the case of capillary, rotating, and porous electrodes. They used a spark excitation source. All three methods of introducing a solution into the spark gap are more or less alike as regards their sensitivity, as well as their accuracy. The mean arithmetical error of reproducibility amounts to $\sim 4\%$. ✓

TITLE: On the Simultaneous Observation of Combination Scattering of Light and of Fluorescence (Ob odnoremennom nablyudenii kombinatsionnogo rasseyaniya sveta i fluorestsentsii)

PERIODICAL: Doklady Akademii nauk SSSR, 1958, Vol. 121, Nr 1, pp. 70 - 73 (USSR)

ABSTRACT: The investigation of many compounds with various types of electron excitation levels is important for a further study of the relations between the scattering of light and fluorescence. The present paper examines the spectra of 4-nitro-4'-amino stilbene

$H_2N-CH=CH-NO_2$ and of 4-nitro-4'-dimethylamino stilbene $Me_2N-CH=CH-NO_2$. According to melting point and adsorption spectra both substances showed the trans-form. Nitro-amino stilbene has a very intensive absorption band in the range from 4000 to 4500 Å and gives a strong fluorescence when irradiated by such wave lengths. Nitro-dimethylamino stilbene exhibits similar spectra. Two

Card 1/3

On the Simultaneous Observation of Combination
Scattering of Light and of Fluorescence

SOV/20-121-1-18/55

tables contain data on the position of the maximum of the absorption band, the position of the maximum of the fluorescence band, the quantum yield of the fluorescence, the mean life of the excited state, the molecular absorption coefficient at 4358 Å, and the frequency of the symmetrical oscillation of the nitro-group in the spectrum of the combination scattering of the two substances mentioned above. The simultaneous observation of combination scattering and of fluorescence is the most important result. The determination of the quantum yield of fluorescence which is excited by various frequencies shows that the observed edge of the absorption band corresponds with the transition which is responsible for the fluorescence. The same electron transition seems to be responsible for the lines of the combination scattering as well. A phenomenon of fluorescence which proceeds relatively slow (including afterglow) and independently of this a quick process of scattering seem to be connected with the long-life electron level. The frequency of the nitro-group is, in the derivatives of nitro stilbene investigated in this paper, lower by $3 - 5 \text{ cm}^{-1}$ than in the case of non-

TITLE: Raman light scattering and lifetime of excited states

SOURCE: Optika i spektroskopiya, v. 15, no. 2, 1963, 176-181.

TOPIC TAGS: spectral line intensity, absorption band displacement, Raman spectrum, organic substance light interaction, organic-solution spectrum

ABSTRACT: Resonance Raman spectra of two diphenylpolyenes $C_6H_5(CH=CH)_5C_6H_5$ and $C_6H_5(CH=CH)_6C_6H_5$ having absorption bands with a clearly expressed vibrational structure have been investigated for the case in which the frequency of the oscillating light penetrates various zones of the vibrational structure of the absorption band. Comparison of the results obtained with data for compounds having a wide structureless absorption band, for which the average lifetime of excited electron-vibrational states is apparently much shorter, shows that 1) the intensity coefficients of Raman scattering lines are much greater, 2) the intensity of harmonics and composite frequencies is unusually high, and as a result lines of the 2nd, 3rd, and 4th order have been observed, and 3) there is a very

Card 1/2

L 17308-63
ACCESSION NR: AP3005897

sharp increase in the intensity of lines when the exciting frequency approaches the region of intensive absorption (particularly by harmonics). In scattering, absorption, and fluorescence, the spectra appear to be normal and similar nuclear oscillations, and, consequently, the change in the equilibrium values of normal nuclear coordinates under conditions of electronic excitation is the most important for all three cases. When the temperature of solutions decreases, the line intensities of Raman scattering of diphenylpolyenes change more sharply than in nonresonance spectra; in addition, the displacement of absorption bands is of the greatest importance. Orig. art. has: 2 figures and 5 tables.

AUTHOR: Shorygin, P. P.; Ivanova, T. M.TITLE: Molecular light scattering and lifetime of excited states

SOURCE: AN SSSR. Doklady, v. 150, no. 3, 1963, 533-536

TOPIC TAGS: Raman effect, lifetime of excited states, band spectra, diphenyl-polyenes, fluorescence of organic molecules

ABSTRACT: The purpose of this study was the elucidation of the interaction between light and molecules. The Raman spectra of compounds with a large lifetime of electron-vibrational energy levels can give the intensity of the fundamental frequency and of overtones, the widths of the lines, and the degree to which the normal vibrations are the same in the absorption-, scattering-, and fluorescent spectra. The resonance Raman spectra of the diphenylpolyenes $\text{Ph}-(\text{CH}=\text{CH})_n-\text{Ph}$ were studied in this work, particularly those of diphenyldecapentaene $\text{Ph}-(\text{CH}=\text{CH})_{10}-\text{Ph}$ and diphenyltridecapentaene $\text{Ph}-(\text{CH}=\text{CH})_{13}-\text{Ph}$ in an acetone solution which were excited with H_2 -lines of wave numbers of 24,700 and 24,986 cm^{-1} . The experimental curves for the absorption coefficient vs. the wave number as well as the Raman and fluorescence spectra for these two compounds are given. The

Card 1/2

L 10833-63

ACCESSION NR: AP3000747

spectra were obtained at 25C; the absorption spectra at -70C and the secondary spectra at -196C are also given. At a lower temperature, the intensity of these Raman spectra changes much more than in the non-resonance spectra. This is attributed to the increase of the lifetime of the corresponding levels and to the shift of the absorption bands. Other peculiarities of the secondary spectra are also described. Orig. art. has: one figure and two tables.

TITLE: Vibrational and electronic spectra of ethers of polyene carboxylic acids

SOURCE: Ref. zh. Fizika, Abs. 4D426

REF. SOURCE: Tr. Konis. po spektroskopii. AN SSSR, t. 3, vyp. 1, 1964, 113-124

TOPIC TAGS: ir spectrum, Raman spectrum, uv spectrum, carboxylic acid, electron spectrum, vibration spectrum, conjugate bond system

ABSTRACT: In order to study the mutual influence of functional groups of atoms through a system of conjugated bonds, the authors investigated the frequencies and integral intensities of the IR, Raman, and UV bands of polyene compounds of the type $X(CH=CH)_nCOOC_2H_5$ ($X = CH_3, OC_2H_5, COH, NO_2,$ and $COOC_2H_5; n = 1 - 5$). On the basis of an analysis of the obtained data, the authors explain the causes of variations of these parameters and of the spectra of the compounds in the ground and excited states. TITLE:

On the System Polyphenols - Polyphenol Oxidase in Cabbage
(O sisteme polifenoly - polifenoloksidaza v kapuste)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 125, Nr 1, pp 213-215
(USSR)

ABSTRACT:

With respect to their oxidation systems plants can be divided into polyphenol-oxidase- (potato, cotton, apple tree with the mentioned ferment being highly active) and in peroxidase-plants (cabbage, onion etc). In the latter group ascorbic oxidase plays the part of the final oxidase. It is functionally related with peroxidase. The authors observed that in the case of being infected with Botrytis cinerea the color of the cabbage tissues becomes dark. It is well-known that the oxidation products of polyphenols play an important part in both the changing of color and the resistivity of the plants to parasites (Ref 2). This is why the experiments with phenol compounds were carried out on white cabbage "Amager" and "Nr Pervyy" (Nr one). The phenol compounds and phloroglucine were quantitatively determined according to the methods of references 3 and 4 (Table 1). Thus, it can be seen that the cabbage tissues are

Card 1/4

On the System Polyphenols - Polyphenol Oxidase in
Cabbage

SOV/20-125-1-59/67

rich in tan, i. e. much richer (by the four-fold) than potato tubers (Ref 5). The tanning complex of cabbage is also far more varied than that of potato tubers. Apart from water-soluble tans (50%) cabbage contains also alkali-soluble tans, further in both fractions also free ether-soluble polyphenols. 15-20% of the water-soluble fraction are free polyphenols, the rest being easily mobile, uncomplicated compounds. According to Kursanov they are depsides - the most simple ones in the group of condensed tannides (Ref 3). The remaining 50% of tans in cabbage consist of complicated compounds with a high molecular weight. They are insoluble in water and can only be separated after the addition of a 1% alkali lye (Ref 6). Pyrocatechin and pyrogallol groups are lacking in all fractions. By means of paper-chromatography small amounts (0.3-0.5 mg/%) of caffeic acid and chlorogenic acid (pyrocatechin derivatives) were discovered (in accordance with Ref 7). All fractions contained phloroglucine - a polyphenol with hydroxyl groups in meta-position (18 and 24% in the water and alkali-soluble fractions, respectively). It was also present in free state in the cabbage tissues (in accordance with Ref 4). Table 2 shows data

Card 2/4

On the System Polyphenols - Polyphenol Oxidase in
Cabbage

SOV/20-125-1-59/67

concerning the role of the phenol compounds, in particular with respect to their taking part in oxidizing processes. Among the substrates investigated phloroglucine was the only one to be oxidized by cabbage tissue. This oxidation is suppressed by specific inhibitors of the copper-containing ferments (Table 3). From table 4 it can be seen that the addition of ascorbic acid increased the oxygen-absorption somewhat in case that phloroglucine was substituted. Table 5 shows that phloroglucine is very intensively oxidized by suspension as well as by sections from cabbage. In this connection phloroglucine for itself is twice as intensively oxidized as ascorbic acid for itself. Together, the substances were much slower oxidized. For the time being, the conclusion may be drawn from the above mentioned data that polyphenols with a meta-position of the hydroxyl groups (as phloroglucine) may often take active part in the redox-processes in plant tissues. The initially mentioned division of plants (Ref 1) has therefore probably no absolute importance. There are 5 tables and 7 references, 6 of which are Soviet.

TITLE: Peroxidase activation mechanism in infected tissues of immune plants

SOURCE: Prikladnaya biokhimiya i mikrobiologiya, v. 1, no. 1, 1965, 25-36

TOPIC TAGS: enzyme, plant disease, agriculture crop, toxicology, protein, spectrophotometric analysis, plant chemistry, immunity

ABSTRACT: Peroxidase activity changes were investigated in a variety of cabbage sensitive to *Botrytis cinerea* and in a variety resistant to it. In a series of experiments, one half of a cabbage leaf was infected with a natural or synthetic *B. cinerea* toxin and the other half served as a control. Specimens were tested 3 to 4 days later. Protein fractions were isolated for spectrophotometric analysis and peroxidase activity was compared. Findings show that peroxidase activity increases by 1.5 times in the infected leaves of the resistant variety, but decreases in the leaves of the sensitive variety. The peroxidase consisted of two

ACC NR: AP6009016

components. The first component (first peak) accounted for 87% of the peroxidase activity in the resistant variety, and differences between the two components were considerably smaller in the sensitive variety. The effects of natural and synthetic B. cinerea were approximately the same. Control leaves of the resistant variety sustaining a cut but no infection also displayed increased peroxidase activity, and responded to toxin infection at a later date with an even higher increase. Increased peroxidase activity of the resistant cabbage variety appears to be related to new formation of specific proteins in the resistant tissues. Certain protein fractions of B. cinerea toxin also display peroxidase activity; but, their effects are insignificant inasmuch as tests demonstrated that both natural toxin and boiled toxin increase peroxidase activity. The authors conclude that increased peroxidase activity in infected tissues of a resistant variety represents a specific immunity reaction. Orig. art. has: 6 figures and 11 tables.

TITLE: Determination of niobium and tantalum in wolframites

SOURCE: Zhurnal analiticheskoy khimii, v. 22, no. 1, 1967; 164-167

TOPIC TAGS: niobium, tantalum, spectrographic analysis

ABSTRACT: A rapid quantitative method was developed for the direct spectral determination of niobium and tantalum in wolframites. A DFS-13 spectrograph was employed. Artificial mixtures simulating the composition of wolframites were used because no natural wolframites containing very low amounts of Nb (0.005-2%) and Ta (0.01-2%) were available. Nb and Ta were determined by the method of three standards using the analytical lines Ta 2635.9 - Mo 2672.8 and Nb 2671.9 - Mo 2672.8. The sensitivity of the method was 0.01% for Ta₂O₅ and 0.005% for Nb₂O₅. This is not the limit for the proposed method, but at lower contents, Ta and Nb will have to be separated from the bulk of tungsten if the spectral determination is to succeed. Authors regard it as their pleasant obligation to thank V. F. Barabanov for providing the wolframite samples and for his constant interest in this work. Orig. art. has: 5 tables:

TITLE: Fungus-resistant effect of phenols and their role in plant immunity

SOURCE: AN SSSR. Doklady, v. 164, no. 3, 1965, 705-708

TOPIC TAGS: plant chemistry, plant injury, fungus, phenol, paper chromatography

ABSTRACT: The presence of higher levels of water soluble phenol compounds in infected tissues of resistant varieties of plants prompted the present study. A resistant variety of cabbage (Amager) and a nonresistant variety (No. 1) were infected with Botrytis cinerea and were freeze dried to determine the role of phenols in fungus resistance. Extracts were derived from tissues of healthy and infected plants by boiling for 30 min, filtering, and boiling again. Following paper chromatography, toxicity of the separated phenol compounds was determined by their effect on the growth of B. cinerea mycelia. Findings show that toxic substances are present in infected cabbage leaves, with a higher concentration found in the more resistant cabbage variety. Paper chromatograms for infected plant tissues indicate the presence of five spots completely different from the two spots found for healthy

Card 1/2

L 4294-66

ACC NR: AP5024223

plant tissues. Two substances exerting a toxic effect on B. cinerea found in the infected tissues of the resistant variety of cabbage are identified as spot number 4 and spot number 6 and appear to be of a phytoalexin nature. The chemical composition of spot number 4 is not known as yet, but spot number 6 is identified as vanillin whose toxic effect on B. cinerea has been demonstrated. The presence of vanillin appears to be related to the breakdown of lignin in infected cabbage leaves. No conclusions are drawn and the study will be continued.
