TITLE: Adrenaline-like Substances and the Biological Activity of Blood in the Case of Cold Essay Under Normal Conditions and Those of Diencephalic Pathology (Adrenalinopodobnyye veshchestva i biologicheskaya aktivnost' krovi pri kholodovoy probe v usloviyakh normy i diencefal'noy patologii)

PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 126, Nr 2, pp 446-449 (USSR)

ABSTRACT: The state of the vegetative nervous system is to a certain extent characterized by the different forms of the adrenaline-like substances. On the other hand it is impossible to gain by only one determination of the chemical composition and the biological properties of blood a conception concerning the "homeostase" boundaries or the structure of the pathological syndrome as the latter is always a combined expression of pathological processes and compensation phenomena. The main principle of the collective group of the authors is a dynamical investigation of the human organism: of a healthy, a sick, and a recovering one. The authors did not restrict themselves to the determination of a physiological or biochemical final

SOV/20-126-2-61/64

Adrenaline-like Substances and the Biological Activity of Blood in the Case of Cold Essay Under Normal Conditions and Those of Diencephalic Pathology

constant but tried to find the adaptation mechanisms of the organism and to separate the primary from the secondary reactions which are so important for the origin, course, and result of a disease. The authors used the method of the adrenaline-like substances and of the biological blood activity before and after the stress in order to characterize the reactivity of the nervous system. In the present paper the results are given which were obtained by cooling down the experimental person's hand. Healthy persons (control) and such affected with different forms of diencephalic pathology (Refs 5, 6) served for this purpose. With practically healthy persons the cold essay lead to an increase in the sympathetic blood activity. It was expressed by an increase of the positive inotropic effect on an isolated frog heart (an average of 40-50%). The acetyl-choline level in blood was reduced by an average of 40%. In most cases the content of reversibly reduced adrenaline-like substances and more rarely of the specificity coefficient (SpC) increased. Thus the primary reaction of healthy persons is in the case of a cold stress the activation of the sympathetic adrenal apparatus. The

Adrenaline-like Substances and the Biological Activity of Blood in the Case of Cold Essay Under Normal Conditions and Those of Diencephalic Pathology

sick persons can be divided into 4 groups according to the results: Ist g r o u p . The reaction does not differ considerably from the normal reaction. Often there occur, however, considerable shifts which surpass the physiological fluctuations of the content of the investigated substances. Mainly persons with functional disturbances of the activity of the regulatory hypothalamus nerves were concerned. The disease is curable in spite of the patients' complaints and shows a favorable course. IInd g r o u p . The sympathetic activity (accumulation of "sympathines") increases here, the adrenaline-like substances increase, sometimes also the SpC in the case of a simultaneous increase in acetyl-chinoline. IIIrd. g r o u p . The sympathetic blood activity and the acetyl-chinoline decrease are reduced. An additional heat essay is recommended (Ref 4). IVth g r o u p . The sympathetic blood activity is reduced. Reduction of the adrenaline-like substances, sometimes reduction of SpC. Acetyl-chinoline increases (Fig 2). This occurs in severe diencephalic pathology and is scarcely curable. The increase in the sympathetic blood activity can depend on the accumulation of the adrenaline-

Adrenaline-like Substances and the Biological Activity of Blood in the Case of Cold Essay Under Normal Conditions and Those of Diencephalic Pathology

like substances, on the transition of the oxidized forms to reduced ones, but also on the reduction of the "parasympathine" level. The increase in "parasympathine" level is often connected with the reduction of the sympathetic activity. There are 1 figure and 7 Soviet references.

TITLE:

Gastric Reception and Control of Food Behaviour in Dogs
(Retseptsiya zheludka i regulyatsiya pishchevogo povedeniya
u sobak)

PERIODICAL:

Doklady Akademii nauk SSSR, 1959, Vol 126, Nr 3, pp 692 - 695
(USSR)

ABSTRACT:

The statement that an excess or lack of different substances in the inner part of the organism is able to influence specifically such a complicated behaviour reaction as the food selection is based upon the hitherto collected facts. The investigation of the mechanisms which secure such influences is in this connection very necessary. The osmoreception and possibly the reception of other blood components is caused by the carotid nodules (karotidnyye klubochki) according to several present observations. It is, however, as well possible that a chemical analysis of the substances introduced into the organism occurs already earlier in the bowel before they are absorbed by the blood (Refs 1, 3-5). The authors tried to explain in

Card 1/3

in Dogs

SOV/20-126-3-65/69

this connection the possibility of specifically reflex influences of the intestine interoceptors of higher animals on their food behaviour. Approximately 250 experiments were carried out with 8 dogs which had gastric fistulas. A soundproof chamber or an isolated room served this purpose. 15 ml solution with an equal quantity of milk, however, with different sodium chloride concentrations were offered to the dogs in 4-8 containers. A cover was removed from the food containers before each experiment so that the dog could choose the milk-salt solutions. The taken solutions flowed out again through the gastric fistula which was opened during this interval. The stomach was rinsed with warm water after each experiment. First a salt concentration was detected above which the dogs refused the solutions. Only dogs were chosen in the case of which this maximum concentration remained constantly on the same level. NaCl, glucose, et al. were introduced into the stomach by the fistula. Already after the first experiments it became obvious that the food reaction changes after the introduction of 300 - 500 ml hypertonic NaCl solution (3-5%). In 2 - 3 cases the dogs refused the most concentrated NaCl solutions in milk (Fig

Card 2/3

Gastric Reception and Control of Food Behaviour
in Dogs

SOV/20-126-3-65/69

1). Sometimes the reaction was so distinctly marked that the dogs drank pure milk. The selection reaction was changed in almost all experiments in which a NaCl solution of 5 or 3% had been introduced into the stomach by the fistula. The reaction occurred after only 3-5 minutes, sometimes 15-20 minutes and more. The above mentioned reaction could be stopped neither by filling the stomach with 300-500 ml water nor by expansion by means of an introduced balloon. The change in the reaction vanished, however, after repeated experiments with water filling or expansion by means of a balloon. The mentioned phenomena are of reflex nature. Figure 2 shows that the introduction of 300-500 ml glucose- or saccharose solution does not influence the selection of milk-salt solutions. The change in the selection is realized under the participation of afferent systems of the nervus vagus, although also other centripetal ways play a certain rôle (in line with reference 2). There are 2 figures and 5 references, 3 of which are Soviet.

AUTHOR: Kalyatskiy, I.I.; Kassirov, G.M.

TITLE: Investigation of the effect of electrode material on pulse breakdown of a high-vacuum gap

SOURCE: Zhurnal tekhn.fiz., v.34, no.2, 1964, 348-351

TOPIC TAGS: breakdown, pulse breakdown, high-vacuum breakdown, electrode material, graphite electrode, lead electrode, copper electrode, aluminum electrode, steel electrode, aluminum steel electrode

ABSTRACT: The breakdown of a 1 mm high vacuum gap between a 20 mm diameter hemispherical cathode and a plane anode was investigated with voltage pulses having rise times from 0.2 to 4 microsec. A pressure less than 2×10^{-5} mm Hg was maintained in the gap, and electrodes of graphite, lead, copper, aluminum and steel were investigated. The pulses were produced by discharge of a 100 kV capacitor, and the rise times were controlled by an R-C circuit. The potential across the gap was measured and the breakdown was observed with an oscilloscope. The breakdowns occurred during the rise of the pulse, and the earlier, the steeper the pulse. Breakdown

Card 1/3

ACCESSION NR: AP4013427

times of 0.1 microsec were achieved with all the electrode materials. The 0.1 microsec "pulse coefficient", i.e., the ratio of the breakdown potential at 0.1 microsec delay to the static breakdown potential, ranged from 1.93 for copper to 2.9 for graphite electrodes. Except for the steel electrodes, which did not follow this rule, the pulse coefficient increased with decreasing Young's modulus of the electrode material. The curves of breakdown potential versus delay time were convex to the time axis, except for steel electrodes. The steel electrode curve was slightly concave. Breakdown between aluminum and steel electrodes was investigated, each material serving in turn as anode. The breakdown potential for very short delay times was approximately that characteristic of the anode material, and the shape of the delay time curves was reminiscent of that obtained when both electrodes were of the cathode material. It is considered difficult to reconcile the observed short delay times with Cranberg's hypothesis concerning vacuum breakdown (L.Cranberg, J. Appl.Phys.23,518,1952) because of the long time required for a material particle to traverse the gap. "In conclusion, the authors express their gratitude to engineer B.M.Koval'chuk for participating in the preliminary experiments." Orig.art.has: 3 figures and 1 table.

TITLE: Investigation of delay times for the electric breakdown in vacuum gaps

SOURCE: Zhurnal tekhnicheskoy fiziki, v.34, no.3, 1964, 484-487

TOPIC TAGS: breakdown, electric breakdown, vacuum breakdown, vacuum gap, breakdown delay time

ABSTRACT: The breakdown of positive sphere (12 mm diameter) to plane electrode gaps in vacuum was investigated. The electrodes were of copper and were carefully cleaned and polished. The gap length was varied from 0.1 to 1.0 mm. The vacuum chamber was of metal; the gaps were thus presumably in darkness. The residual gas pressure was between 10^{-5} and 2×10^{-5} mm Hg. No cold trap was employed to remove the pump oil vapor. The voltage pulses were produced by discharging a capacitor bank through a pressure gap into a 75 ohm cable. A voltage doubler (not described) was employed at the open end of the cable. The rise time of the pulse is said to have been 4 or 5 nanosec. The oscillograms reproduced show, however, that the pulse rose in two stages: the voltage rose in 4 or 5 nanosec to half its final value and re-

Card 1/2

ACCESSION NR: AP4020577

mained nearly constant at this value for 10 or 12 nanosec, after which it again rose in another 4 or 5 nanosec to its final value. The delay times were measured from the instant the voltage pulse reached its full value to the time at which the gap potential had dropped by 10%. The delay times were measured at overvoltage coefficients (ratio of pulse voltage to static breakdown potential) up to 1.7. They ranged from about 32 nanosec for the 1 mm gap at an overvoltage coefficient of 1.1 to about 6 nanosec for all gaps at an overvoltage coefficient of 1.7. The relation between overvoltage and delay time was approximately linear. The relation between delay time and gap length at fixed overvoltage coefficient was nonlinear: the delay time increased much more rapidly with gap length for gap lengths near 0.4 mm than for either longer or shorter gaps. This behavior is discussed very briefly in terms of the role of cathode field emission in the breakdown mechanism. "In conclusion, the authors express their gratitude to Assistant Professor I. I. Kalyatekiy for his constant interest in the work." Orig.art.has: 4 figures.

AUTHOR: Kalyatskiy, I.I.; Kassirov, G.M.

TITLE: Investigation of pulse flashover of several solid dielectrics in vacuo

SOURCE: Zhurnal tekhnicheskoy fiziki, v.34, no.8, 1964, 1471-1475

TOPIC TAGS: insulating material, flashover, sparkover, dielectric, particle accelerator

ABSTRACT: In order to obtain data that might be useful in the design of accelerators and other high-vacuum high-voltage equipment, the authors measured the vacuum pulse flashover (sparkover) potentials of teflon, a vinyl plastic, an epoxy resin, and an acrylic resin for pulse durations from 0.1 to 3 microsec. The apparatus is described elsewhere (I.I.Kalyatskiy and G.M.Kassirov, Izv.VUZov, Fizika No.4, 1963). The flashover always occurred during the rise of the pulse. The only information given concerning pulse shape is a single oscillogram; in this case flashover occurred while the pulse was still rising at about half its initial rate. The specimens were 1.5 cm diameter cylinders from 0.5 to 2 cm long. The surfaces were worked with fine emery paper, polished, washed with benzene and alcohol, and the specimens were placed

1/3

ACCESSION NR: AP4042937

in the discharge chamber between 4.5 cm diameter aluminum electrodes. The specimens were subjected to a cleansing discharge, and the flashover potentials were measured both with increasing and with decreasing pulse duration. The flashover potential increased with the length of the specimen, but not quite proportionately. Pulse factors (ratio of pulse to steady spark potential) of 2 to 5 were obtained with 0.1 microsec pulses. At 1.5 microsec the pulse factors, except for teflon, were less than 1.65. These pulse factors are close to those obtained for ceramic materials under similar conditions by M.Kofoed (Power Apparatus and Systems No.6,999,1960). Although for most of the materials the pulse factor decreased monotonically with increasing pulse duration, for Plexiglas the pulse factor reached a minimum of 1.33 at about 1.5 microsec and increased to approximately 2 at 3 microsec. The authors suggest that some of the other materials may have similar minima at longer pulse durations, beyond the range of their measurements. Measurements were made with polished aluminum, ground aluminum, and graphite electrodes; no differences were found. Reducing the cathode diameter to 1.5 cm increased the flashover potential for short pulses by a factor 2; reducing the anode diameter had very little effect. Specimens with carefully polished surfaces flashed over at a 30 to 40% lower potential than those whose surfaces had been worked with fine emery. Orig.art.has: 6 figures.

ACCESSION NR: AP4042938

AUTHOR: Kassirov, G.M.; Mesyats, G.A.

TITLE: On the breakdown mechanism of short vacuum gaps

SOURCE: Zhurnal tekhnicheskoy fiziki, v.34, no.8, 1964, 1476-1481

TOPIC TAGS: spark ignition, electric breakdown, vacuum breakdown

ABSTRACT: The experimental work of G.M.Kassirov and B.M.Koval'chuk (ZhTF 34, No.3, 1964) on the pulse breakdown of 0.1 to 1 mm vacuum gaps has been continued. New experimental results are reported, and the earlier results are reviewed. The salient experimental facts adduced are the following: 1) There is a delay of 5 to 30 nanosec between application of the pulse and initiation of the breakdown. This delay time increases nonlinearly with increasing gap length and decreases with increasing overvoltage. 2) After initiation of the breakdown, the gap potential falls approximately linearly to zero over a decay period of 3 to 40 nanosec. The decay period increases with increasing gap length, and it also increases with increasing overvoltage. 3) The linear decay of the gap voltage is interrupted in the case of the longest gaps by fluctuations which, in the case of the longest gaps, assume an almost os-

1/3

ACCESSION NR: AP4042938

oscillatory character with periods from 5 to 10 nanosec. The work of A.Maitland (J. Appl.Phys.32,2399,1961; Brit.J.Appl.Phys.13,122,1962) on pitting of vacuum gap electrodes is reviewed briefly. An attempt is made to provide theoretical explanations for the experimental results described above with the aid of concepts derived from Maitland's findings. To explain the delay time, the authors assume that Maitland's electron beam issuing from a "micropoint" on the cathode has reached its critical intensity by the time the pulse has risen to its maximum, and they calculate the time required for the beam to vaporize a portion of the anode and eject a puff of anode metal vapor. This time they regard as the delay time. For gaps of 0.3 mm and less the calculated delay times are of the same order of magnitude as the observed, and they behave similarly with varying overvoltage. For longer gaps the observed delay times are much longer than the calculated. The authors suggest that in these cases the electron beam does not reach its critical intensity at once, and that the time required for the development of the beam must be included in the calculation. The explanation of the transition to the arc discharge (decay time) is more involved. The suggestion of M. and A.Goldmann (Compt.rend.Acad.Sci.255,23,2654,1961) that the transition occurs when metal vapor traverses the gap as a result of its explosive ejection from the anode is untenable, for the process is too slow. Ions, on the other hand, traverse the gap in a time much shorter than the observed decay times. The

2/3

ACCESSION NR: AP4042938

authors suggest that when Maitland's electron beam ejects a puff of anode metal vapor, some ions are formed and a narrow conducting channel results. It is assumed that this channel somehow stimulates the development of other electron beams in its vicinity. The process then continues as a chain reaction and thus accounts for the fluctuations of the electrode potential during the decay period. When the overvoltage is increased, the electron beams become narrower and produce smaller electrode pits and fewer conductive channels. More channels are then required to lower the gap potential by a given amount, and their production requires more time. Orig. art.has: 10 formulas, 3 figures, and 1 table.

REF. SOURCE: Sb. Proboy dielektrikov i poluprovodnikov., M.-L., Energiya, 1964, 91-93

TOPIC TAGS: dielectric breakdown, vacuum, spark gap

TRANSLATION: Results are described of experiments on the ^{21,} breakdown of vacuum gaps up to 1 mm under the influence of voltage pulses of duration 0.1 -- 3.0 μ sec. It is shown that the prior conditioning of the gap, namely the number of pulses and the size of the current in each pulse, exerts an appreciable influence. To obtain a relatively stable value of the breakdown voltage, the gap must be broken down beforehand some 200 -- 300 times. Measurements of the volt-second characteristics of a preconditioned gap between a hemisphere

Card 1/2 2

L 22274-56

ACC NR: AR6005191

and a plane show that the polarity of the hemisphere plays an important role. If it is positive, the breakdown voltage of the gap is 10 -- 15% higher in the entire range of discharge-time variation than in the case of a negative polarity. Experiments have confirmed the previously observed appreciable influence of the distance between electrodes on the shape of the volt-second characteristic: at a distance of 0.3 mm no discharge delay appears, and at a larger distance (0.7 mm) a decrease in the voltage duration increases the breakdown voltage.

ABSTRACT: The results are described of an experimental study of breakdown of vacuum gaps up to 1-mm long with 0.1--3.0-microsec impulses. An essential effect of training (number of impulses and their currents) is shown. Relatively stable breakdown-voltage values were obtained only after the gap had been broken 200--300 times. A heavier-current training results in a lower breakdown voltage; hence, the heavy current training was selected. A volt-second characteristic of a trained gap between a hemisphere and a plane was measured; the effect of hemisphere polarity was observed: with a positive polarity, the breakdown voltage was by 10--15% higher than with a negative polarity. The experiments corroborated some earlier data on the effect of the interelectrode distance upon the volt-second characteristic shape: with a 0.3-mm gap, no discharge lag was observed; with longer gaps (0.7 mm), higher breakdown voltage corresponded to shorter time of voltage application. TITL: Effect of electrode material on the breakdown time of a vacuum gap

SOURCE: Zhurnal tekhnicheskoy fiziki, v. 36, no. 10, 1966, 1883-1885

TOPIC TAGS: spark gap, vacuum, electric discharge, electrode, steel, copper, graphite, aluminum, lead

ABSTRACT: The author has employed high voltage square pulses and apparatus and techniques described elsewhere by himself and B.M.Koval'chuk (ZhTF, 34, 484, 1964) to measure the delay times in the breakdown of vacuum gaps with electrodes of steel, copper, aluminum, graphite, and lead. The potentials giving equal delay times for 0.5 mm gaps with electrodes of graphite, aluminum, copper and steel increased in the order in which the electrode materials are named. This finding is in agreement with the results of N.B.Rozanova and V.L.Granovskiy (ZhTF, 26, 490, 1956). When the delay times were plotted against the overvoltage, the curves for the different electrode materials fell into three groups: for steel, copper, and graphite, the delay time at an overvoltage of 1.2 was 18-20 nanosec; for aluminum the delay time at the same overvoltage was about 8 nanosec; and for lead the delay time was less than 5 nanosec and could not be measured. The following semiempirical equation for the

UDC: 537.521.7

Card 1/2

ACC NR: AP6033426

delay time t in terms of properties of the electrode material, based on the theory of A. Maitland (J. Appl. Phys., 32, 11, 2399, 1961), is presented: $t = (\pi C k s T^2 d^{6/5}) / (L k^2 v^3)$. In this equation, C is the heat capacity, k is the heat conductivity, s is the specific gravity, and T is the melting point of the electrode material, d is the gap length, v is the pulse breakdown potential, and K is a constant whose value is $6.8 \times 10^5 \text{ erg/V}^{1.5} \text{ cm}^{1.4} \text{ sec}$. Abstracter's note: The author does not say what L represents. This formula is shown to be in very rough agreement with the experimental data. It is concluded that thermal processes at the anode play an important role in the process of vacuum gap breakdown. Orig.art. has: 1 formula, 2 figures, and 2 tables.
