TITLE: Electrophoretic filter for reactor water purification

SOURCE: Atomnaya energiya, v. 19, no. 4, 1965, 350-354

TOPIC TAGS: nuclear research reactor, nuclear reactor ~~operation~~, water purification equipment, ~~water-cooled nuclear reactor~~, industrial filter, electrophoresis, corrosion, stainless steel / VVR-M nuclear reactor, 1Kh18N9T stainless steel

ABSTRACT: In January, 1962, a formation of turbidity in the primary loop of the VVR-M reactor of the Physicotechnical Institute im. A. F. Ioffe, AN SSSR, was observed. In June, the turbidity was so strong that a special electrophoretic filter for water purification was installed. The turbid water contained a 54-pct-suspension of hydrate aluminum oxide which was originated by the corrosion of aluminum reactor vessel and fuel-element cans. A daily amount of about 2 g/MW of suspended particles was discharged into the water. The installed filter was equipped with the platinized titanium anodeplates, while the cathode

O
plates were made of 1 18.9T stainless steel. A cylindrical prototype of the filter was experimentally tested and the results were explained and graphically illustrated. The tests showed that the chemical composition of turbid and filtered water was as follows:

	<u>Turbid</u>	<u>Filtered</u>
Al ₂ O ₃ in m/kg	3.0	0
Fe+3 " "	0.4	0.18
SiO ₂ " "	6.0	1.3
O ₂ " "	0.96	2.96
Optical density	0.065	0.008

The selected filter design data are summarized in the following table:

Water flow rate in kg/hr	250-500
Effective water flow in cu m/hr	0.5
Electrode voltage in v	110-220
Distance between electrodes in cm	1
Contact time in min. (at 250 l/hr)	2
Total filter volume in liter	10.7
Interelectrode volume in liter	7.5
Electrode size in mm	170x572
Number of anode plates	4
Number of cathode plates	5
Filter dimensions in mm	400x224x935

Card 2/3

ACC NR: AP5026440

The filter has a small hydraulic resistance and needs only about 0.5 kw for its operation. A flow diagram represents schematically the circulation of water in the primary loop of the reactor. Another figure shows a photo of the electrophoretic filter which was successfully used for purifying water in the VVR-M reactor. The authors express their gratitude to Academician B. P. Konstantinoff for his continuous interest. Expressions of thanks are also given to V. P. Rodzevich (for apparatus design), V. D. Trenin and R. N. Rodionov (for analysis) and to D. A. Yashin and B. S. Razov for their assistance. Orig. art. has: 2 tables and 6 figures.

Title : Anomalous Light Diffusion in Glas

Orig Pub : Optika i spektroskopiya, 1956, 1, No 7, 907 - 916

Abstract : The indicatrices of Rayleigh diffusion of 6 specimens of sodium-borosilicate glass were studied, an anomalously high grade dependence of the diffusion intensity on the wave length of the incident light having been observed in them. The specimens differed more than 1,000 times by the opalescence magnitude. The diffusion was measured at wave lengths of the incident light of 546, 578 and 436 $\mu\mu$ and at two orientations of the polarization of the initial beam. When the initial beam is polarized in the diffusion plane, the indicatrices increase monotonously with the angle. When it is polarized perpendicularly to the diffusion plane, the indicatrices have a minimum, which is

Title : Anomalous Scattering of Light in Glass

Orig Pub : Dokl. AN SSSR, 1956, 109, No 1, 64-67.

Abstract : The author has determined the scattering indicatrices of light at various wavelengths λ of the visible spectrum in specimens of opalescent sodium borosilicate glass with an opalescence that differs by a factor of more than 1000. The observed anomaly lies in the fact that in all cases the intensity of the backward scattered light has exceeded by a factor of many times the intensity of the light scattered forward. The corresponding ratios of the brightness varied from 5.5 to 55, reaching a maximum in specimens with a medium degree of opalescence. These results, which contradict the classical theory of Rayleigh

PURPOSE: This book is intended for researchers in the science and technology of glasses.

CONTENT: The book contains the reports and discussions of the Third All-Union Conference on the Viscous State, held in Leningrad on November 16-19, 1959. They deal with the methods and results of studying the structure of glasses, the relation between the glass structure and properties of glasses, the nature of the chemical bond and glass structure, and the crystallochemistry of glass. Fused silica, mechanism of verification optical properties and glass structure, and the electrical properties of glasses are also discussed. A number of the reports deal with the dependence of glass properties on composition, the tinting of glasses and radiation effects, and mechanical properties and soda borosilicate glasses. Other papers treat glass constituents and soda borosilicate glasses. The Conference was attended by more than 300 delegates from Soviet and East German scientific organizations. Among the participants in the discussions were N.V. Solomin, Ye. V. Kirzhanskiy, Yu.A. Gavrilov, V.F. Prosvintsev, Yu. Ya. Gold, O.P. Nefedov-Petrozayev, G.P. Mikhaylov, G.M. Petrov, A.N. Lazarev, D.I. Levin, A.V. Shatilov, M.F. Plotnikinskii, A.Ya. Kurnakov, E.V. Dobryakov, G.V. Bursenkova, A.A. Kaledin, M.H. Skornyakov, P.Ya. Poloz, E.M. Pol'skaya, Ye.A. Kurnakov, V.P. Podolny, R.S. Shevchenko, Z.G. Plankier, and O.S. Holtschawow. The final session of the Conference was addressed by Professor I.F. Kitayevsky, Honored Scientist and Engineer, Doctor of Technical Sciences. The following Institutes were invited for their contributions to the development of glass science and technology: Gosudarstvennyye opticheskiye institut (Gosopticheskiy Institut), Institut khimii silikatov Akademii Nauk (Institute of Silicate Chemistry, AS USSR), Fizicheskiy institut Akademii Nauk (Physical Institute of USSR), Fiziko-tehnicheskii institut Akademii Nauk (Physico-Technical Institute of USSR), Zavodskiy fizicheskiy institut Akademii Nauk (Institute of Physics, Academy of Sciences, Belorussian SSR, Minsk), Minsk (Institute of Physics, Academy of Sciences, Belorussian SSR, Minsk), Laboratoriya po fizicheskoy chistyayushchosti i neorganicheskoy khimii Akademii Nauk, Minsk (Institute of Chemical and Inorganic Chemistry, Academy of Sciences, Belorussian SSR, Minsk), Institut vysokomolekulovyykh soedinenii Akademii Nauk (Institute of High Molecular Compounds, AS USSR), Gosudarstvennyy nauchno-tekhnicheskiy institut akademii Nauk (State Institute for Glass), Goucharovskiy nauchno-tekhnicheskiy institut Akademii Nauk (State Institute for Electrical Glass), Sibirskiy fizicheskicheskii institut (Siberian Physical-Chemical Institute), Novosibirskiy nauchno-tekhnicheskiy institut (Novosibirsk Institute of Chemical Technology, Novosibirsk), Institute of Chemical Technology (Leningrad State University), Leningradskiy khimicheskicheskicheskii institut (Institute of Chemical Technology, Leningrad), Leningradskiy tekhnologicheskii institut (Institute of Chemical Technology, Leningrad), Leningradskiy tekhnologicheskii institut im. Lenina (Leninskii Tekhnicheskii Institut im. Lenina), Leningradskiy politekhnicheskii institut Minsk (Belorussian Polytechnic Institute, Minsk), Minsk (Borishevskiy Politekhnicheskii institut (Borishevskiy Polytechnic Institute), and Sverdlovskiy politekhnicheskii institut (Sverdlovsk Polytechnic Institute). The Conference was sponsored by the Institute of Silicate Chemistry Akademii Nauk (Acting Director - A.S. Gotlib), the Vsesoyuznyye khimicheskkiye obshchestva i sotrudnichestvo (All-Union Chemical Society Joint D.R.), Fizicheskii i tekhnologicheskii institut (Institute of Physics and Technology), and the Goucharovskiy nauchno-tekhnicheskiy institut (Institute of Chemical Technology, Leningrad).

S.I. Vasil'eva (State "Order of Lenin" Optical Institute, Senior R.J. Vasil'eva). The 35 resolutions of the Conference include recommendations to organize a Center for the purpose of coordination of the research on glasses, to publish a new periodical under the title "Tekhnika i khimiya skla" (Technology and Chemistry of Glass), and to join the International Committee on Glass. The Conference thanks A.I. Avgutdin, Academician, Professor, and Chairman of the Organization Committee; Ye.A. Porya-rozhitsa, Doctor of Physics and Mathematics, Member of the Organizational Committee; and R.L. Nyuller, Doctor of Chemical Sciences, Member of the Organizational Committee. The editorial board thanks G.M. Barterov, M.V. Volkenshteyn, L.I. Peakin, S.K. Dubrovin, D.R. Dobychin, V.A. Iorke, and B.T. Kolomyets. References accompany individual reports.

AUTHOR: Kolyadin, A.I.

TITLE: Anomalous scattering of light in glass

PERIODICAL: Referativnyy zhurnal. Fizika, no. 7, 1961, 163, abstract 7016 (V sb
"Stekloobrazn. sostoyaniye". Moscow-Leningrad, AN SSSR, 1960, 230-
233, Discus., 238 - 242).

TEXT: Anomalous scattering in opalescent sodium-boron-silicate glasses and some other glasses consists in the following phenomena: at the absence of absorption and small refraction index of the separated phase, intensity of back scattering of light in optical range exceeds forward scattering by a factor of several scores, the exponent of wavelength dependence of scattered light intensity is close to 7, and the exponent of an analogous dependence of integrated scattering coefficient varies between 4 and 8. This anomalous scattering is explained by that the element of scattering particle, being excited later, oscillates in this case relative to the element of the same particle excited earlier with a phase lead. The author considers a simple model of two coupled oscilla-

TITLE: Small-angle scattering of light in ruby and leucosapphire single crystals

SOURCE: Fizika tverdogo tela, v. 8, no. 11, 1966, 3254-3259

TOPIC TAGS: small angle scattering, ruby, sapphire, light scattering

ABSTRACT: Small-angle scattering of light was studied in one leucosapphire and one ruby sample of cylindrical shape with zero orientation of the axis, i. e., in which the optic axis of the crystal was parallel to the geometric axis of the cylinder and was at the same time the growth axis, and also in two leucosapphire samples and several ruby samples with a 90° orientation of the optic axis. The measurements were made with a small-angle nephelometer. It was found that in both types of orientation, scattering takes place mainly in the direction perpendicular to the electric vector, the ordinary ray being scattered at larger angles than the extraordinary ray. For both types of rays, the scattering coefficients in the planes of the electric vector are one order of magnitude smaller than the corresponding coefficients in the perpendicular plane. The scattering coefficients in the plane perpendicular to the electric vector for the extraordinary ray decrease more slowly with increasing angle than

TITLE: A device for measuring the scattering coefficient of radiation. Class 42,
No. 187356

SOURCE: Izobreteniya, promyshlennyye obraztsy, tovarnyye znaki, no. 20, 1966, 137

TOPIC TAGS: light scattering, radiation, measuring instrument, optic system

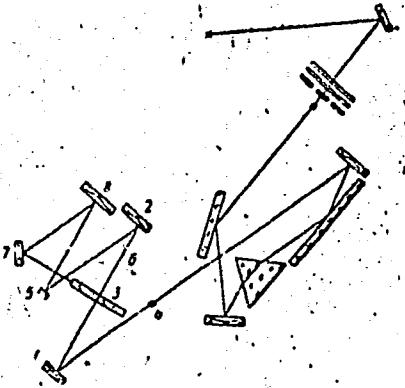

ABSTRACT: This Author's Certificate introduces: 1. A device for measuring the scattering coefficient of radiation. The installation contains a radiation source and receiver, monochromator and optical system for projecting the stream of radiation on the input slit. The range of angles at which the scattering coefficient can be measured in radiation of fixed wavelengths is expanded by using an optical system consisting of a parabolic and a spherical mirror or two spherical mirrors with the specimen between them in the form of a plane-parallel plate. The output slit of the monochromator is located at the main focus of the first mirror, while the radiation receiver is placed at the focus of the second. This receiver is mounted so that it may be moved in the focal plane. 2. A modification of this device for measuring radiation scattering coefficients at an angle of 90° to the surface of the specimen.

TITLE: A "Spectrovisor"

PERIODICAL: Optika i spektroskopiya, 1960, Vol. 9, No. 2, pp. 253-256

TEXT: The authors describe a fast spectrophotometer (shown schematically in Fig. 1) which traces simultaneously the transmission coefficient spectra of a test and a standard sample on the screen of a cathode-ray tube. The spectrophotometer is suitable for the visible region and its speed can be judged from the fact that each transmission curve is traced in 0.01 sec. Twelve photographic records can be made in one second and this makes it possible to study fast chemical reactions, such as the reaction between solutions of furfural and aniline in acetone (Fig. 2). There are 2 figures. X

TITLE: High-speed two-cell spectrophotometer for the spectral region 0.23 - 1.0 micron 39

SOURCE: Ref. zh. Metrologiya i izmeritel'naya tekhnika, Abs. 9.32.833

REF SOURCE: Tr. Komiz. po spektroskopii. AN SSSR, vyp. 1, 1964, 643-649

TOPIC TAGS: spectrophotometer, spectrophotometry, spectral distribution

ABSTRACT: A high-speed two-cell spectrophotometer with mechanical scanning of the spectrum is described. The curve of the spectral transmission coefficient of the investigated object, the 100% line, and the zero line can be produced on the screen of an oscilloscope. The spectral range of the device of 0.23-1.0 μ is divided into three spectral segments. The spectral transit time is 0.05 sec. Recording is produced with a movie camera with a rate of 24 frames/sec. The kinetics of chemical and photochemical reactions can be investigated with the device. High-speed spectrophotometry of investigated objects can also be produced. Illustrated. Bibliography of 2 citations. [Translation of abstract]

Distribution of Radio Elements in the Sediments of the Black Sea.
(USSR)

TITLE: Doklady Akademii Nauk SSSR, 1959, Vol. 129, Fr. 5, pp 1142-1145

ABSTRACT: The radioactivity of the sediments in the enclosed seas is almost unmeasured. The Black Sea above characteristic hydrological and hydrochemical conditions. It is also inherently rich with sedimentary material. For this reason its sedimentation strongly differs from that in large oceanic waters (Ref. 5). In this connection the authors wanted to explain the influence of these specific conditions on the sedimentation and the type of distribution of the radio elements in the Black Sea bottom sediments. The results achieved are not sufficient to draw final conclusions. For this reason only some observations are presented. The authors studied the vertical distribution of uranite, radium, iron, thorium, iron, and calcium in a sediment core which was taken from the central part of the Black Sea from a depth of 215 m. It was 22 cm long and consisted mainly of gray brown genesis clay with 5 intermediate sand strata. The upper 18 cm

consisted of extremely fine-dispersed mud with thin irregular intercalated strata. Figure 1 shows the vertical distribution of the above-mentioned elements in the core. Table 1 gives the corresponding figures. From these data it may be concluded that in the upper horizon of the core the radioactive equilibrium in the uranium series is widely disturbed; the iodine content is at least 4 times higher than the amount corresponding to the equilibrium with uranium. The radium content, however, constitutes only 1/4 of this amount. The radium content in the water of the Black Sea is only 1/5 of the equilibrium value of uranium dissolved in the water. Thus the radium content in the sediment is hardly one fourth of the amount which should be measured if 45% of the radium were sedimented from the water. Assuming that no radium migration takes place in the cores of marine sediments (Ref. 1), the difference in the radium content in the water and in the sediment of the Black Sea may be explained by radium leaching from the sediment. On the other hand, the upper horizon of the core contains considerably more calcium and uranium. Their content increases toward the bottom rapidly and then practically remains constant. According to F. M. Shchukin more than 90% of CaCO_3 were sedimented by chemical

method. The main bulk of iron, however, is transported into the deposited sediments with the river water. The authors conclude therefore that the vertical CaCO_3 -distribution reduces the change of the chemical conditions in the core of these cores to a very great extent and the total amount of carbon dioxide in the solution is separated from the solution. On the other hand, it can be concluded from the parallel change in the thorium content with that of iron that the major part of thorium is of terrestrial origin. The authors calculated the rate of sedimentation in the Black Sea from the data from Table 1. It is 12-15 cm within thousand years. If it is however assumed that 1/2 the horizon 100-100 on the equilibrium between iodine and uranium is still attained (Fig. 2) the rate of sedimentation is only 0.4-0.5 cm per 100 years. The problem as to which of the two values is correct has hitherto not been definitely solved. There are 2 figures, 1 table, and 6 references, 4 of which are Soviet.

Black SeaPERIODICAL: Doklady Akademii nauk SSSR, 1960, Vol. 132, No. 6,
pp. 1411 - 1412

TEXT: It follows from an introductory survey publication that a fairly equal distribution is to be found in the oceans, an average of $2.7 \cdot 10^{-6}$ g/l. Strong deviations from this concentration can occur in coastal waters and inland seas. The Black Sea has a special position among those that are related to the ocean. The exchange of water with the ocean is limited, mineralization is diminished, and the water is contaminated with H₂S up to the upper 125-175 m. It is to be assumed that under these conditions, hexavalent uranium is reduced to a state of pentavalency. This should lead to active uranium sedimentation and

a change in concentration in the depths. Table 1 correlates data from 1951 and 1958 (central and western parts of the Sea). Uranium was determined by a luminescence method from 0.3 - 11 samples with an accuracy of + 20%. The authors draw the following conclusions from Table 1: 1) the uranium concentration fluctuates in the samples examined between $1.5 \cdot 10^{-6}$ and $2.8 \cdot 10^{-6}$ g/l. 2) These variations occur on the surface as well as in the depths. No regularity in these concentration changes could be detected. Thus the specific reductive milieu of the Black Sea from 125-175 m upwards remains without influence on the distribution of the uranium concentration. According to approximate calculations, the average concentration of uranium in the part of the Black Sea examined is $2.0 \pm 0.3 \cdot 10^{-6}$ g/l, which approaches the average value in the ocean. The decline in concentration in the Black Sea does not exceed 30-35%, while the mineralization is lowered by 54% in comparison to the ocean. The authors thank I. Ye. Starik, Corresponding Member AS USSR, in whose laboratory the work was carried out. There are 1 table and 16 references: 2 Soviet, 7 American, 1 Swedish, 1 Japanese, and 3 Austrian.

TOPIC TAGS: water, air, respirator, diving mask, naval physiology

ABSTRACT: An Author Certificate has been issued for a breathing device for divers working at constant depths. It consists of a housing with a mask and inhaling and exhaling valves; it is connected to the breathing bag of the device regulating the required gas volume. The breathing bag has a bleeder valve joined to a regenerative cartridge containing a chemical substance, and to a cartridge containing a chemical absorbent. To insure that the diver can remain under water at constant depths for a long period, the component regulating the required gas

volume in the breathing bag is in the form of a housing with channels. The housing is joined to the exhalation tube by a regenerative cartridge and a cartridge containing a chemical absorbent. The housing contains a valve rest contacting an elasticized membrane mounted inside the housing and attached to the elastic walls of the breathing bag by flexible trip rods. The housing automatically distributes the flow of exhaled gas to the regenerative and absorbent cartridges. Orig. art. has: 1 figure. [Translation] [N-67-2]

TITLE: On the Packing Mechanism of Flange Joints Using Rubber Linings

PERIODICAL: Kauchuk i Rezina, 1960, No. 10, pp 29-34

TEXT: The authors conducted a study of the packing ability of ring-shaped linings with a rectangular cross-section compressed between groove flanges in sharp pressure drops. The loss of airtightness of these linings in the flange grooves takes place by the contact mechanism but, according to the authors, this phenomenon has not been dealt with sufficiently. Comparisons were also made by studying ring-shaped linings of rectangular cross-section compressed between flat flanges. Tests were made on linings with the following dimensions: internal diameter $d = 24$ mm, external diameter $D = 44$ mm, height of lining $h = 9$ mm. The form factor $\Phi(F)$ calculated according to the formula $(D-d)4h$ was 0.55. The linings were prepared from 4 types of rubber with the following compositions: 1) CKB (SKB), carbon black (60 weight parts to 100 weight parts of raw rubber), captax, sulfur; 2) CKC-30 (SKS-30), carbon black (30 w.p. to 100 w.p. of raw rubber), thiuram; 3) SKS-30, carbon black (100 w.p. to 100 w.p. of raw rubber), altax $\Delta\Phi\Gamma$ (DFG), sulfur; 4) CKH-26 (SKN-26).

On the Packing Mechanism of Flange Joints Using Rubber Linings

carbon black (110 w.p. to 100 w.p. of raw rubber), thiuram, sulfur. Fig. 1 represents the relationship of the actual tension to the degree of compression of the tested rubbers in static deformation. The tension was measured every 3 minutes from the moment the given value of compression was reached. The obtained measurement data were used to calculate the static rubber modulus E and lining modulus E' according to the formula: $E' = E (1 + \alpha F)$ where $\alpha = 0.5$ (Ref. 6). Table 1 gives the values of the moduli of the rubbers and the linings and also the rubber hardness according to Shore. The linings were tested on a stand at air pressure of 200 atm and 20°C. The attachments containing the linings were placed into a water bath. The lack of airtightness was noted by the appearance of air bubbles. Fig. 3 gives the data on the effect of the degree of compression of the linings located between the flat flanges on the value of the critical working pressures (i.e., the pressure whereby the lining loses its airtightness). The packing ability of the linings compressed between the flat flanges depends on the degree of compression and the rubber modulus. If the lining modulus E' and the degree of compression ϵ are known, the specific compression load can be calculated $f = E' \epsilon / (1 - \epsilon)$ (Ref. 6). The conclusion

Card 2/8

S/138/60/000/010/005/008
A051/A029

On the Packing Mechanism of Flange Joints Using Rubber Linings

is drawn that the specific compression load of the lining is a function of the modulus and degree of compression of the lining and therefore determines its packing ability. By changing the hardness of the rubber or the degree of compression of the lining the necessary flange tension can be obtained which would determine the value of the critical working pressure in the system of flat flanges. The critical nature of the loss of airtightness is explained by the decreasing dependence of the lining's resistance on the radial shift. Since the resilient resistance force of the lining in the first moment of the radial shift is equal to zero, therefore the loss of stability is determined by the value of the friction force. This explains the reason for increasing the friction coefficient in using flange linings. Experimental findings are listed to confirm the conclusions drawn and to explain the effect of certain factors on the self-packing phenomenon of rubber lining. The size of the clearance between the lining and internal wall of the caliber was determined mathematically. Obtained data lead to these conclusions: 1) self-packing occurs in the presence of any clearance between the lining and the limiting ring, but the value of the critical compression ϵ_k depends on the size of the clearance. 2) With an increase in the clearance ϵ_k the critical compression

Card 3/8

S/138/60/000/010/005/008
A051/A029

On the Packing Mechanism of Flange Joints Using Rubber Linings

increases (or the critical specific load of self-packing f_k). With an increase in the hardness of the rubber the critical compression load f_k increases and at zero clearance the self-packing takes place at a load f_k on the flanges which differs from zero and is the higher, the harder the rubber (Fig 7). It is stated that for linings between flat flanges under high pressure one should apply high-modulus rubbers. For linings in groove flanges the low-modulus rubbers should be used, since it is important that the packing begin at as low a pressure as possible on the flanges. Summarizing the experimental results the authors conclude that the packing of the rubber linings compressed between groove flanges (or with a lock) at low compressions takes place according to the same mechanism as that of the flat flanges (loss of stability). In high compressions increasing with the hardness of the rubber, self-packing occurs. The magnitude of the diameter clearance between the lining and the wall of the groove on the side opposite to the pressure has a significant effect on the packing ability of the linings located between the groove flanges. The greater the clearance, the more the self-packing phenomenon is noted at high compressions. For linings located between flat flanges the critical hydraulic

Card 4/8

A051/A029

On the Packing Mechanism of Flange Joints Using Rubber Linings

pressure of the loss of airtightness is a function of the flange tension (specific load of compression of the lining) and hardly depends on the type of rubber. In the case of linings located in the grooves the critical working pressure of self-packing to a greater extent depends on the hardness of the rubber and the size of the diameter clearance. There are 7 graphs, 1 table, 1 diagram and 7 references: 6 Soviet, 1 English.

TITLE:

Effect of low temperatures on the hermetic sealing capacity of rubber linings

PERIODICAL: Kauchuk i rezina, no. 9, 1961, 27 - 31

TEXT: A study was conducted on the effects of low temperatures on the critical pressure of loss of sealing and on the contact tension of compression of the linings. It was noted that with a drop in temperature the hardness of the rubber sharply increases (Fig. 1). The contact tension (i.e., the resilience of the metal) drops with a drop in the temperature, whereas the hardness of the rubber increases (Fig. 2) due to the fact that the measured contact tension is the equilibrium tension of the compressed rubber or close to it. It decreases with a drop in the temperature. Rubber linings of CK5(SKB) showed an increase in the compression module with a drop in temperature from 20 to -60°C, i.e., by 6 times; a drop in the contact tension in the same interval by a factor of about 2 and an increase in the critical pressure of loss of sealing by about 6 - 7 times (Fig. 4).

Card 1/53

S/138/61/000/009/007/011
A051/A129

Effect of low temperatures on the...

The sealing properties of the linings are not characterized by the magnitude of the contact tension, which is explained by an increase in the friction force and hardness. Experiments to test the relative role played by these two factors in elevating the stability of the rubber linings at low temperatures using lubricated surfaces of contact between the rubber lining and the flange indicated that a drop in the friction reduces the critical pressure of sealing loss. An increase in the critical pressure with a drop in the temperature for linings with non-lubricated surfaces is explained by the increase in friction. Linings compressed between flat flanges with a loss in the sealing capacity, have a critical pressure which increases with a drop in the temperature, since the magnitude of the contact tension also drops. An increase of the critical pressure with a drop in the temperature is noted up to a certain critical temperature T_{cr} , below which the lining loses its sealing capacity. The critical pressure drops to zero at temperatures of vitrification T_g . Lubrication of the contact surfaces with low-temperature lubricants causes the temperature dependence on the critical pressure to drop sharply, which indicates the important role played by the friction force in the stability of the lining. The increase in the critical pressure within the region of low temperatures, up to T_{cr} , is explained by an increase in the friction

coefficient (which is sharper than the drop of the contact tension); and partially by the increase in the lining hardness. All the obtained results indicate that the contact tension in itself does not determine the critical pressure of sealing loss, neither at low nor at elevated temperatures. There are 7 figures and 7 references: 6 Soviet-bloc and 1 non-Soviet-bloc. The reference to the English-language publication reads as follows: R. E. Morris, J. W. Hollister, A. E. Barrott, Ind. Eng. TITLE: The self-sealing phenomenon in hermetic-sealing units with rubber linings

PERIODICAL: Kauchuk i rezina, no. 5, 1962, 29 - 33

TEXT: A study is made of the change in contact tension of a rubber lining during its application in flanges with restricting rings which, in turn, take the place of a lining in the sealing units with groove or lock. An attachment was designed for this purpose (Fig. 1), where the contact tension can be measured directly in the sealing unit under any pressure. The attachment has two flanges (1, 2), connected through bolts. A restricting caliber (3) is placed into the lower flange, serving as a wall of the groove or lock. The working pressure is applied through the lower flange (compressed air). In the upper flange, at the point of contact with the lining, there is an aperture into which a rod (4) is placed, with a base area of 0.07 cm^2 . The free motion of the rod, within a range of 0.01 mm, is limited above by a metal screw (5), and below, by

Card 1/3

A051/A126

The self-sealing phenomenon in hermetic-sealing

contact (6), installed with a textolite screw (7), so that it is electro-insulated from the upper plate. The tension is measured by the compensation method. The effect of the lining under lubrication was studied. The pertinent parameters are then treated. The following general conclusions were drawn: Beginning at a certain critical value of the pressure of the sealing medium, a phenomenon is noted which is self-sealing with a transfer of the excess pressure of the working medium to the flanges, according to Pascal's law. When working with groove-type flanges, the friction force should be reduced by lubricating the contact surfaces, since this promotes the occurrence of the self-sealing effect at lower working pressures of the sealing medium.

TITLE: Effect of residual deformation on highly-elastic regeneration of rubber at low temperatures

PERIODICAL: Kauchuk i rezina, no. 10, 1962, 28 - 31

TEXT: A study was made of rubber properties affected by accumulation of residual deformation, namely, the effect on the highly-elastic regeneration of rubber samples or rubber sealing parts. The causes of residual deformation accumulation are not analyzed. Both accumulation of residual deformation at high temperatures and "freezing" of the highly-elastic deformation at low temperatures cause the negative effect of a decrease of the highly-elastic regeneration. The mathematical calculation of various parameters and graphs plotted from experimental results are presented. It was found that the experimental data agree well with the computed values. The authors conclude that the frost-resistance of commercial rubber sealing parts depends not only on the frost-resistance of the rubber, but also on the degree of accumulation of residual deformation dur-

USSR/Medicine - Modification of Microorganisms; Dysentery

"Investigation of Filterable Forms of Bacteria Isolated From Dysentary Phage Filtrates," V. D. Timakov, R. S. Mikhel'son, L. S. Kolyaditskaya, A. A. Shnurygina, Inst of Epidem and Microbiol im N. F. Gamaleya, Acad Med Sci Ussr.

Zhur Mikro, Epid, i Immun, No 11, pp 5-11

Secondary cultures obtained from phagolysates of dysentery bacilli were not very active. They could be regenerated by repeated culturing on a nutrient medium. Secondary culture No 23 exhibited a common antigenic structure with the initial strain. By cross-agglutination, the mutual resemblance of antigenic structures of different secondary cultures as well as of secondary initial strains could be shown. The immune serum obtained by immunizing rabbits with a secondary culture protected mice from lethal doses of the culture and of the initial strain. Animals immunized with the initial strain were more resistant to a homologous culture than to secondary cultures. Immunization with secondary cultures did not assure complete protection against the initial strain, while there was pronounced resistance to homologous cultures.

AUTHOR: Kolyadnyy, S.

TITLE: On the Book "Gas Resources of the USSR"

PERIODICAL: Geologiya nefti i gaza, 1960, No. 4, pp. 56-57

TEXT: The author writes a critique of the book "Gazovyye resursy SSSR" ("Gas Resources of the USSR"), to which A. N. Kortunov, P. Ya. Antropov, and V. A. Kalamkarov contributed in addition to the main authors, Yu. I. Bokserman, A. A. Borisov, I. O. Brod, V. G. Vasil'yev, N. D. Yelin, N. S. Yerofeyev, N. M. Kudryashova, M. S. L'vov, M. F. Mirchink, A. T. Muratova, N. V. Nevolin, V. L. Sokolov, and A. A. Trofimuk. In the introduction, A. N. Kortunov gives a grand picture of the planned gas supply to the most important industrial areas of the USSR; this will influence the fuel balance of the country during the next few years decisively. P. Ya. Antropov describes the successes and the future tasks of geological exploration and prospecting during 1959-1965. V. A. Kalamkarov describes the role of natural gas and oil in the fuel balance of the USSR and deals with the necessity to develop various branches of industry and their conversion
