TITLE: Dispersity of chemically reduced powdered metals as a function of the potential of the reducing agent

SOURCE: Elektrokhimiya, v. 1, no. 9, 1965, 1103-1106

TOPIC TAGS: powder metal production, copper, silver, titanium compound, vanadium compound, chromium compound, iron compound, particle size

ABSTRACT: The magnitude of the redox potential of a system

used for the production of metal powders determines its reducing power and at the same time determines the rate of formation of powdered metal. With increase of the negative potential or lowering of the positive value of the potential of the system one would also expect an increase in the rate of the occurrence of crystal active centers which would in turn result in an increase of the dispersity of the powdered metal. The following redox systems were considered:  $Ti^{3+}/Ti^{4+}$  ( $E^\circ = 0.04$  v),  $V^{2+}/V^{3+}$  ( $E^\circ = -0.25$  v),  $Cr^{2+}/Cr^{4+}$  ( $E^\circ = -0.41$  v) in the production of powdered

copper and  $\text{Fe}^{2+}/\text{Fe}^{3+}$  ( $E^\circ = +0.771 \text{ V}$ ),  $\text{Cr}^{2+}/\text{Cr}^{3+}$ ,  $\text{Ti}^{3+}/\text{Ti}^{4+}$  in the production of powdered silver. The concentration of copper was always constant (0.114 N). Powdered copper was produced by mixing equal volumes of the above copper sulfate solution in the presence of  $\text{H}_2\text{SO}_4$  (100 g/l) with the appropriate redox system. The rate of mixing and the temperature of the solutions was maintained constant for all experiments. The metal deposit was washed and stored in acetone for sedimentation analysis. In an acetone medium the small particles were not aggregating and the highly dispersed copper and silver deposits formed fine stable suspensions. The method for the calculation of the distribution curves of powders according to particle size was described by Tsyurupa ('Khimicheskaya promyshlennost', No. 3, 1961). The maximum on the distribution curve for copper where  $\text{Cr}^{3+}$  was used as a reductant corresponds to  $0.322 \mu$ , for the  $\text{V}^{2+}/\text{V}^{3+}$  system it is  $0.408 \mu$  and for the  $\text{Ti}^{3+}/\text{Ti}^{4+}$  system it is  $0.5 \mu$ . For the system with silver powder  $\text{Cr}^{2+}$  produces a maximum on the distribution curve at  $0.336 \mu$ . The mean calculated radius for silver powder reduced with  $\text{Ti}^{3+}$  is  $0.5 \mu$  and it is  $1.16-1.39$  when  $\text{Fe}^{2+}$  is used as a reductant. The sedimentation analysis data are in good agreement with microphotography at 1000 magnification. It is thus concluded that the dispersity of powdered metals produced by chemical reduction is directly related to the potential of the system.

TITLE: Effect of accelerations on hepatic structure

SOURCE: Konferentsiya po aviatcionnoy i kosmicheskoy meditsine, 1963.  
Aviationsnaya i kosmicheskaya meditsina (Aviation and space medicine);  
materialy\* konferentsii. Moscow, 1963, 303-307TOPIC TAGS: acceleration effect, hepatic structure, transverse acceleration,  
hepatic injury, dog

ABSTRACT: Dogs were exposed to transverse accelerations of 8 g for 3 minutes and 12 g for 1 minute. Histological examination of liver sections indicated the presence of two facets of hepatic injury: vascular injury and injury of the hepatic cells and bile ducts. The former was in the form of a distention and a frequent rupture of the hepatic blood vessels, while the latter was characterized by hemorrhages, followed by necroses at the site of extrav-

Card 1/2

ACCESSION NR: AT4042696

sations. In addition, a frequent expulsion of the nucleoli into the cytoplasm of the hepatic cells was observed, accompanied by an increase in liquid and pigment inclusions. The conclusion is reached that the degree of hepatic injury is directly proportional to the magnitude of acceleration and the exposure time.

TITLE: Effect of a single exposure to acceleration on the structure of the viscera in experimental animals

SOURCE: AN SSSR. Otdeleniye biologicheskikh nauk. Problemy\* kosmicheskoy biologii, v. 3, 1964, 297-305

TOPIC TAGS: dog, acceleration, histology, hemorrhage, rupture

ABSTRACT: Two groups of dogs were exposed to transverse accelerations of 8 g and 12 g for 3 min and 1 min, respectively. Selected animals were then killed after 1 hr, and after 1, 3, 5, 7, 15, 30, and 60 days. Sections of the viscera of the animals killed were stained with a variety of stains. The most striking histological features observed in all organs were 1) increases in vascular permeability and 2) frequent ruptures. These changes led to such obvious consequences as hemorrhages and inflammations. It is stressed, however, that all of the observed changes were reversible, as evidenced by the perfectly normal histological picture of the remaining animals.

Title : Compounds of Trivalent Iron Sulfate with Sulfur Dioxide.

Orig Pub : Roczn. Chem. 1956, 30, No 3, 697-708

Abstract : The composition of kinetics of the reduction of complex compounds  $\text{Fe}_2(\text{SO}_4)_3$ , which are formed in solutions with pH 2.8-3 containing  $\text{SO}_2$ , and in solutions containing in addition the basic sulfates of Al (I) have been investigated. The existence of complexes with molar ratios  $\text{Fe}:\text{SO}_4$  equal to 2 and 3 has been established. The existence of complexes with  $\text{Fe}:\text{SO}_2$  ratios equal to 1.5 and 6 is also possible. At a constant maintenance of  $\text{Fe}^{3+}$  and  $\text{SO}_2$  in the solution, the concentration of the complexes increases with the growth of the I concentration. Since it has been already demonstrated before (Bretsznajder S., Przem. Chem. 1936,

Card 1/2

POLAND/Inorganic Chemistry - Complex Compounds.

C.

Abs Jour : Ref Zhur - Khimiya, No 11, 1958, 35667

20, 253), that the higher the I concentration in the solution the larger the portion of  $\text{Fe}^{3+}$  salt to be found in the form of basic sulfate, the authors assume that in the complexes in question  $\text{SO}_2$  is connected with the basic Fe sulfate. The complexes decompose rather fast due to the  $\text{Fe}^{3+} \rightarrow \text{Fe}^{2+}$  reduction. In the presence of I the decomposition proceeds as a reaction of the second order. In solutions not containing I, the decomposition proceeds at a faster rate, and according to a reaction of a fractional order.

TITLE: Effect of vagotomy on aldosterone secretion in the dog

SOURCE: Academiae scientiarum hungaricae. Acta physiologica, v. 28, no. 2, 1965, 163-170

TOPIC TAGS: corticosteroid, dog, endocrinology

ABSTRACT: A study was carried out on the effect of vagotomy on the rate of aldosterone secretion in hypovolemic and hypervolemic dogs. The rate of secretion achieved in the hypovolemic state was significantly increased by vagotomy. In the hypervolemic state, vagal section had no effect on the aldosterone output of the adrenals. Under such experimental conditions, the inhibitory effect of hypervolemia on aldosterone secretion was overruled by the stimulating effect of blood loss. The authors thank Ciba, Basel and Organon, Oss, Netherlands for supplies of steroid preparations. Orig. art. has: 3 figures. [Orig. art. in Eng.] [JPRS]

"Investigation of the Relation Between the Rennin-Angiotensin System and Aldosterone Secretion."

Budapest, Kiserletes Orvostudomany, Vol XV, No 4, Aug 1963, pages 431-434.

Abstract: [Authors' German summary] In the course of the investigations, rats have been bled from the adrenal vein by the authors. The aldosterone produced by the hemorrhage was determined by a paper chromatographic method. Ligature of the hilus of the kidneys, that is, exclusion of the rennin-angiotensin system, did not influence the increased aldosterone production resulting from the hemorrhage. It is concluded that the increase of the aldosterone production is independent of the rennin-angiotensin system.

A description is given of a laboratory method developed in Czechoslovakia for testing the efficacy of fungicides against wheat bunt (*Tilletia tritici*) [*T. caries*; *R.A.M.*, 17, p. 501]. The materials to be tested (0.2, 0.5, 1, and 5 mg.) were placed in Petri dishes, 5 ml. spore suspension added, and the dishes kept in a refrigerator at 10° C. for six days. The following materials prevented germination at 0.2 mg.: germisan, cereasan, zyma 3, slow, tritisan, and agrosan (IN; agronal allowed occasional germination. The fungicides also gave 90 to 100 per cent. control in field tests.

TITLE: The growth of crystals by the chemical transport  
of material II. Growth of iron whiskers

PERIODICAL: Czechoslovak Journal of Physics, v. 12, no. 9,  
1962, 723-724

ABSTRACT: When studying the epitaxial growth of iron on seed crystals by the method of chemically transporting iron over volatile compounds in a sealed ampoule, we observed that under certain conditions iron whiskers are formed in addition to the formation of epitaxial layers. Since the experimental arrangement employed offers far better possibilities for defining the growth conditions than methods of growing iron whiskers known up to now, we aimed our research work at studying the growth of whiskers under conditions of chemical transport. We chose a transport system in which the transport of iron (from the

warmer to the cooler zone) is brought about by a reversible reaction:  $\text{Fe}_{(s)} + 2 \text{HCl}_{(g)} = \text{FeCl}_{2(g)} + \text{H}_2$ . This system has already been studied from the chemical point of view by Schäfer [1]. The method of measurement was fundamentally the same for all our experiments. Iron filings, prepared by vacuum remelting of powdered carbonyl iron, were placed in one end of a quartz ampoule (reaction zone). Selected iron seed whiskers, prepared by Brenner's standard method [2], were inserted into the quartz stand in the other end of the ampoule (growth zone). These whiskers will be denoted here as "primary" in order to distinguish them from those formed in transport conditions ("secondary" whiskers). Four to six primary whiskers were placed in a row over a section of about 3 cm along the ampoule. The latter was then thoroughly pumped to a high vacuum and, after filling with a measured amount of gaseous hydrogen chloride (about  $4 \times 10^{-6}$  mol.), was sealed off. Transport took place at an average rate of 4-5 mg/h due to the formation of a temperature gradient along the axis of the ampoule (reaction zone).

Card 2/6

The growth of crystals by the chemical...

860° - growth zone: 700°C). At the beginning of each experiment the surfaces of the primary whiskers were always slightly etched by reverse transport in order to remove adsorbed impurities. Under the above conditions we regularly observed the growth of secondary whiskers which nucleated both on the primary whiskers (see Fig. 1)<sup>2</sup> and on the quartz. At the end of the growing cycle (64 hours) they had reached lengths of 6 mm and thicknesses of about 50  $\mu$ . Their cross-section was usually square. It was particularly remarkable that along both edges of the section, in which the primary whiskers were located, the walls of the ampoule were covered with a continuous layer of iron (mirror), while inside this section the walls were only relatively scarcely covered with small crystals and whiskers (Fig. 2). This is a favourable circumstance, permitting observation of growth inside the section in question. In the absence of primary whiskers the walls were covered with an almost continuous layer over the whole length of the growth

2 - - - - -

The growth of crystals by the chemical...

zone while practically no secondary whiskers were formed. Introduced primary whiskers obviously change the supersaturation field inside the ampoule so that the supersaturation at the ampoule walls decreases to a value which is not very far from the critical value for nucleation on quartz glass. Epitaxial layers grew over the whole surface of the primary whiskers simultaneously with the growth of the secondary whiskers. These layers had the same orientation as the substrate and a relatively coarse surface relief, composed of densely ordered pyramids, resembling the surface of germanium crystals, grown in a similar way [3]. In most cases it was not possible to make visible the boundary between the primary whiskers and the epitaxially grown layer by etching the polished cross-section. More exact data cannot yet be given on the kinetics of the growth of secondary whiskers. We expect that the measurement of the growth rates of the individual secondary whiskers, in ampoules supplied with optical windows, will provide more detailed information on the growth mechanism. The transport method, from the point of view of studying the growth of iron whiskers, has a great

Card 4/6

Z/055/62/012/009/005/005

The growth of crystals by the chemical...

advantage in that growth takes place practically in a stationary state, so that supersaturation can be defined (at least for simpler systems such as ours) on the basis of equilibrium data. Existing methods of growing iron whiskers [4-6], based on the reduction of volatile halogenides of iron in a hydrogen stream, have the common drawback that they do not permit the supersaturation in the place where the whiskers grow to be satisfactorily defined. Under reduction conditions in a hydrogen stream quite considerable fluctuations occur in the composition of the gaseous phase in the growth zone. Wiedersich's modification [5] represents an attempt towards approximating steady growth conditions. References: [1] Schäfer H., Etzel K.: Z. anorg. allg. Chem. 301 (1959), 137; [2] Brenner S. TITLE: Growing crystals by the chemical transport method. III. Study of the growth of  $\alpha$ -iron crystals

SOURCE: Czechoslovakia: Fizický časopis, v. 15, no. 1, 1965, 64-70

TOPIC TAGS: crystal growth, alpha iron crystal, crystal face, surface orientation, iron whisker, hydrochloric acid cycle, chemical transport method

ABSTRACT: The method of chemical transport is used for preparing crystals of  $\alpha$ -iron. The epitaxial growth of iron on iron seed crystals (whiskers) is studied during transport in closed quartz ampoules. The influence of a change in characteristic conditions, i.e., of the temperature of the growth zone, the difference in temperatures of the reaction and growth zones, the distance between the whisker and the source, and the kind and concentration of the transport agent, on the quality of the surface of the grown layer is investigated. It was found that the method of chemical transport can be used to prepare larger crystals, bounded by smooth

TITLE: Heterochain polyamides. 34. Synthesis of polyamides with active functional groups in macromolecules

SOURCE: Vy'sokomolekulyarnye soyedineniya, v. 5, no. 7, 1963, 979-985

TOPIC TAGS: polyamides, polycondensation, interfacial polycondensation, macromolecules, functional groups

ABSTRACT: Studies were conducted on the polycondensation reaction of 1,3-diaminopropane-2-ol (DAP) with sebacic acid as well as with sebacyl and terephthalyl chlorides. The polyamide obtained by heating a mixture of DAP with sebacic acid for one hour at not over 200°C yielded a product of low molecular weight. Any further increase in temperature or heating time resulted in the formation of a tridimensional, nonfusible, brittle mass, soluble only in sulfuric acid. On the other hand, interfacial polycondensation of DAP with sebacyl or terephthalyl chlorides in a water-benzene system produced cresol-soluble polymers of substantially higher viscosity, the optimum concentration

Card 1/2

L 13716-63

ACCESSION NR: AP3003786

of DAPO being 0.25 Molar. An excess of DAPO is needed, since it acts as an acceptor for the hydrogen chloride formed during the reaction. The optimal yield of the polymer amounted to 60%, as against 63% where sodium hydroxide was used as acceptor. Mixed polyamides were produced by reacting DAPO with sebacyl chlorides and hexamethylenediamine. Here, too, the use of sodium hydroxide resulted in products of a higher melting point and lower solubility. Orig. art. has: 6 diagrams and 3 tables.

TITLE: Catalytic polymerization of trimethyltriphenylcyclotrisilazane

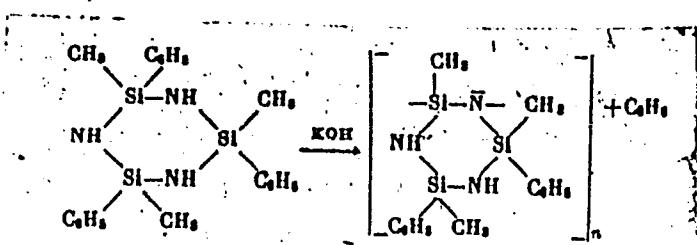

SOURCE: Vyssokomolek. soyedin., v. 6, no. 4, 1964, 691-694

TOPIC TAGS: organosilicon compound, silizane, alkylarylsilazane, cyclosilazane polymerization, chain polymer, chain block cyclic structure, potassium hydroxide catalysis, benzene liberation

ABSTRACT: In an earlier publication by K. A. Andrianov and G. Ya. Rumba (Vyssokomolek. soyed., 4, 1060, 1962) it was shown that (in the presence of alkaline catalysts) dimethylcyclosilazanes, unlike dimethylcyclosiloxanes, undergo polymerization with the formation of polymers having a cyclic structure of the chain block molecule. In the present investigation 10 g of trimethyltriphenylcyclotrisilazane (TTCTS) were heated at 180-400°C in the presence of 1% KOH. This resulted in the liberation of benzene starting at 180°C and increasing with time, according to a polymerization reaction of the type:

Card 1/3

ACCESSION NR: AP4032569

In this way 1.95 g of benzene were obtained from 10 g of TTCTSA within a 5-hour polymerization period at 200°C. Analysis of the obtained polymers revealed an increased silicon content and a lowered amount of carbon at higher temperatures and extended reaction time. The structure of the polymers at the earlier stages of the reaction was found to be linear and to consist of cyclic units presented in the formula, whereas in an advanced stage of polymerization there seemed to have occurred a branching of the molecules. An investigation of the thermomechan-

Card 2/3

ACCESSION NR: AP4032569

ical properties of the polymers revealed a behavior typical of a nonstructurated polymer (without a region of high elastic state). Orig. art. has: 3 tables and 2 charts.

TITLE: Ammonolysis of alkyltrichlorosilanes and aryltrichlorosilanes

SOURCE: AN SSSR. Izvestiya. Seriya khimicheskaya, no. 3, 1966, 472-475

TOPIC TAGS: ammonolysis, silane, organic chemistry, alkyltrichlorosilane, aryltrichlorosilane, polymer, IR spectrum

ABSTRACT: The purpose of this article is to determine the possibility and direction of ammonolysis of alkyl- and aryltrichlorosilanes. The ammonolysis of methyl-, ethyl- and phenyltrichlorosilanes by gaseous ammonia in a solvent medium was investigated. Experiments have shown that instead of the expected branched and crosslinked ammonolysis products, polymer compounds soluble in benzene are produced. Experimental data show that ammonolysis of ethyltrichlorosilane leads to the formation of low molecular cyclic products and cyclic polymers. While ammonolysis of methyltrichlorosilane is similar, branching and structuring of the reaction products takes place. Both soluble and insoluble products are formed. The elemental analyses and IR spectra show that the crystalline substance produced here is an analog of the cyclic compound produced in the

UDC: 546.287 + 542.952

ammonolysis of ethyltrichlorosilane. The ammonolysis of phenyltrichlorosilane does not produce a crystalline compound, but the produced polymers are highly soluble in benzene. Infrared spectra show the presence of Si-NH-Si bonds and Si-O-Si bonds at  $910\text{ cm}^{-1}$  and  $1030\text{ cm}^{-1}$  respectively. This indicates that the elementary link of the produced polymer is  $(C_6H_5)_3Si_3(NH)_{40.5}$ . Study of the thermal properties of polyphenylsilazanes showed that they have a very high vitrification temperature in the neighborhood of  $500^\circ C$ . The article gives experimental details on ammonolysis of the above silanes.

V. N. Kurnikov and L. N. Kubissova. Akim. Zhurn. 1953, No. 414. A study of the effect of pressure, temp., ratio of reagents, and catalyst on the esterification of carboxylic acids with Cl(CH<sub>2</sub>)<sub>2</sub>CH<sub>2</sub>OCH<sub>2</sub>CH<sub>2</sub>OH (I) was made.  $\alpha$ -MeC<sub>6</sub>H<sub>5</sub>SO<sub>3</sub>H, PhN<sub>3</sub>, Me<sub>2</sub>KOH, and NaOH were used as catalysts. Heating CH<sub>2</sub>Cl<sub>2</sub>, CHCl<sub>2</sub>OH, ethylene oxide, and the catalyst in a steel autoclave 5 hrs. gave I, b.p. 62-60°, n<sub>D</sub><sup>20</sup> 1.4300, d<sub>4</sub><sup>20</sup> 0.9525. Yields of 70.7-77.7% were obtained at a molar ratio of ethylene oxide-allyl alc. 1:2.45, a temp. of 120-30°, and in the presence of 5% KOH or NaOH. Esters (II) of I were obtained by heating 6-8 hrs. at 138-40° equimolar quantities of I with the corresponding acid, 5%  $\alpha$ -MeC<sub>6</sub>H<sub>5</sub>SO<sub>3</sub>H, and 0.5% CuCl<sub>2</sub>, cooling, and washing with 5% soda soln., then with water. Thus were prep'd. the following II (acid used and b.p., n<sub>D</sub><sup>20</sup>, and d<sub>4</sub><sup>20</sup> of II given) (dibasic acids gave diesters): maleic, b.p. 157-60°, 1.4710, 1.1015; malonic, b.p. 145-48°, 1.4533, 1.0902; succinic, b.p. 150-8°, 1.4560, 1.0773; adipic, b.p. 180-1°, 1.4590, 1.0531; phthalic, b.p. 190-2°, 1.5053, 1.1270; benzoic, b.p. 120-2°, 1.5073, 1.0737; acetic, b.p. 91-9°, 1.4290, 1.0190; levulinic, b.p. 118-20°, 1.4486, 1.0505. These esters were polymerized in the presence of 5% benzoyl peroxide, at 60-90° for 120 hrs. Only di(allylethylene glycol)maleinate gave a solid polymer. M. Hoseni

TITLE: Production of Goods From Fluoroplast-4 (Pererabotka  
ftoroplasta-4 v izdeliya).  
Investigation of the Preforming Process (Issledovaniye  
protsesssa tabletirovaniya).

PERIODICAL: Khimicheskaya Promyshlennost', 1957, Nr 8, pp. 5-9 (USSR)

ABSTRACT: The investigations concerning the detection of processes for  
the production of goods from fluoroplast-4 were started in  
1949. Foreign references (references 3-6) and the original  
variants of the laboratories of L. V. Chereshkevich (NIIPP)  
and of L. F. Vereshchagin (IOKh AN) were at the disposal of  
the NIIPM where they were produced. The production method  
was divided into the following 4 stages:

- 1) preparation of the pulverulent fluoroplast-4 for  
preforming: a) thermal treatment of the powder, b) aeration  
of the powder.
- 2) Preforming
- 3) Caking together
- 4) Cooling of the finished product. In the investigation of  
the production method the papers of P. P. Balandin
