TITLE: Decomposition of isopropyl benzene hydroperoxide during hydrocarbon oxidation in a homogeneous liquid phase or in an emulsion

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 20, 1961, 321, abstract 20L46 (Sb. nauchn. rabot. In-t Fiz.-organ. khimii AN BSSR, no. 8, 1960, 22-31)

TEXT: The conversion degree of isopropyl benzene (I) into hydroperoxide (HP) at different oxidation degrees of this hydrocarbon was investigated. HP was found to be the only oxidation product in the initial stage of reaction. When the oxidation takes place in an emulsion, the reaction is more intense, and higher concentrations of HP are reached. A study of HP decomposition during the oxidation of I in a homogeneous liquid phase or in an emulsion indicated that rate and mechanism of HP decomposition vary with the degree of oxidation. When the oxidation takes place in an emulsion, the HP decomposition in the oleophase has a similar course as

Card 1/2

B106/B147

Decomposition of isopropyl ...

during the oxidation in a homogeneous liquid phase, and the rate constant of HP decomposition drops with progressing reaction. In the aqueous phase, the decomposition of HP is monomolecular throughout the oxidation of cumene in an emulsion, and the decomposition constant rises with increasing degree of oxidation. If the oxidation in a homogeneous liquid phase is stimulated with cobalt stearate, the decomposition rate of HP rises, and by-products of the reactions are formed in a large quantity. After the precipitation of the catalyst, monomolecular decomposition sets in. The results of the investigation can be explained well by a radical chain mechanism of HP decomposition. TITLE: On the purification of isopropylbenzene by adsorption

PERIODICAL: Zhurnal prikladnoy khimii, v. 34, no. 3, 1961, 598 - 603

TEXT: A method for the purification of isopropylbenzene by means of adsorption was developed to improve the oxidizability of the latter in liquid phase autocatalytic oxidation processes. These processes are very sensitive, especially at the beginning of the reaction, to the presence of impurities in the hydrocarbon. Usually an acid-alkali purification is applied, eventually with subsequent boiling over sodium metal, as recommended by D. D. Grant and C. F. Tipper [Ref. 4; J. Chem. Soc., 640 (1955)]. But also several adsorption methods were suggested in order to remove impurities from hydrocarbons, as isopropylbenzene or others by O. A. Kolmakov et al. [Ref. 9: Tr. po khim. i khim. tekhn., Gor'kiy, 1, 36 (1958)] or N. D. Kazakova and V. G. Gutsalyuk [Ref. 10: Izv. AN KazSSR, ser. khim., 1, 99 (1958)] and also in the Canadian patent 509870. Thus in the present work the adsorption was investigated of some substances dissolved in isopropylbenzene on ACK (ASK), ACM (ASM) silica gel, aluminum oxide "for chromatography" and two types of carbon

Card 1/6

On the purification of isopropylbenzene by adsorption

S/080/61/034/003/009/017

black (from Dasha and Ufa). Also the oxidation rate of isopropylbenzene after purification was estimated. The adsorption of the impurities - thiophene, styrene, phenol, acetophenone and dimethylphenylcarbinol - from isopropylbenzene was studied by the dynamic method. The amount of the non-adsorbed impurity was determined by means of an NTP-2 (ITR-2) nephelometer. Activation of the silica gel was carried out in the usual way by gradual drying at 40, 60, 80 and 110°C according to E. Kh. Iskhakova et al. [Tr. Inst. nefti AN SSSR, 12, 35 (1958)]. The experiments on adsorption of a non-saturated compound (styrene) showed highest adsorption on carbon black. Because of the easier handling, granulated carbon black was used in the further experiments (see tabulated data). Aluminum oxide showed a low adsorption capacity related to non-saturated compounds (styrene) and also for oxygen-containing compounds (acetophenone, dimethylphenylcarbinol). Therefore aluminum oxide was no more investigated. ASM silical gel had a high adsorption capacity for all investigated impurities, but it adsorbs also isopropylbenzene, while ASK silica gel does not adsorb the latter, but shows low adsorption capacity for styrene. Consequently a mixture (2 : 1 by weight) of ASK silica gel and granulated carbon black was tested with isopropylbenzene containing: 0.01% styrene, 0.01% dimethylphenylcarbinol, 0.01% phenol and 0.01% acetophenone. The obtained results were compared

Card 2/6

On the purification of isopropylbenzene by adsorption

S/080/61/034/003/009/017
A057/A129

with values obtained on pure ASM silica gel, consecutive adsorption of granulated carbon black on ASK and ASM silica gel, and the mixture 2 : 1. It can be seen from Fig. 3 that best results were obtained with ASK-carbon black mixture. Hence the latter is the optimum adsorbent for the purification of technical grade isopropylbenzene. Regeneration of the silica gel is carried out by washing with boiling water or steam and subsequent calcination. Kinetic curves (Fig. 4) on accumulation of hydrogen peroxide in liquid-phase homogeneous oxidation of isopropylbenzene obtained after purification by the acid-alkali method show that a lower reaction capacity is obtained in comparison to the product purified by adsorption methods. 5 kg of ASK silica gel and 2.5 kg of carbon black are necessary for the purification of 100 l of isopropylbenzene. There are 5 figures, 1 table and 12 references: 11 Soviet-bloc and 1 non-Soviet-bloc. The reference to the English-language publication reads as follows: D. D. Grant, C. F. Tipper, J. Chem. Soc., 640. (1955).

AUTHORS: Panasyuk, V. V., Kovchik, S. Ye.

TITLE: Effect of a surface active medium on the surface energy of a brittle body

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 146, no. 1, 1962, 82 - 85

TEXT: The effect of water on the development of cracks in silicate glass was studied. The surface energy of a sample plate with thickness h is

$\gamma = (1 - \nu^2) P_k^2 / 2 \pi E h l_k$, where E is Young's modulus, ν is Poisson's ratio, P_k is the critical stress at which a crack of length $2l_k$ starts to expand. Thus γ can be calculated on reading P_k from a strain gage. The authors determined the surface energy in air (γ_0) and in water (γ_w) of glass consisting of 72.7% SiO_2 , 0.37% SO_3 , 1.45% Al_2O_3 , 0.1% Fe_2O_3 , 7.6% CaO , 3.73% MgO , 14.5% Na_2O . γ_0 was between 1800 and 2700 erg/cm^2 (average 2340 erg/cm^2), γ_w was between 1400 and 2000 erg/cm^2 (average 1790 erg/cm^2). The mean ratio γ_w/γ_0 was 76%. There are 4 figures and 2 tables.

TITLE: The effect of some surface active agents on the intensity of the energy of glass destruction

SOURCE: AN UkrRSR. Instytut mashynoznavstva i avtomatyky, L'viv. Vliyanije rabochikh sred na svoystva materialov (Effect of active media on the properties of materials), no. 2, 1963, 116-127

TOPIC TAGS: glass, surfactant, surface active agent, crack, brittle failure, glass destruction, glass destruction energy, solid body destruction

ABSTRACT: The intensity of the energy required for destroying solid bodies, i. e. the work expended for the formation of a unit of a new body surface of the given material, is a very important property of the material itself. This intensity is also important for explaining the process of destruction of solid bodies and the influence of surface-active agents on this process. In this paper, a method is proposed for determining this energy, based on some results of the theory of crack propagation in brittle substances, and the method is applied to the study of silicate and organic glass in dry air and in a surface

1/2

Card

ACCESSION NR: AT4023779

active medium. A split glass fragment was subjected to tensile forces perpendicular to the crack, and the intensity of the plate-destruction energy was considered to be equal to gamma. When this intensity was measured in the presence of different surface active materials, it was found that water significantly lowered γ (by 26%); methyl alcohol lowered it by 15%; while vaseline oil did not lower γ and even increased it in comparison with dry air. These results corroborate to some extent the hypothesis of P. A. Rebinder (Yubileyny*y sbornik, posvyashchenny*y 30-letiyu Velikoy Oktyabr'skoy sotsialisticheskoy revolyutsii, ch. I, Izd-vo AN SSSR, 1947, p. 533) that surface-active substances act in two ways on the deformation and failure of hard bodies. For some materials this effect is expressed by a lowering of gamma, while for others it leads to an increase in gamma. Orig. art. has: 6 figures, 3 tables and 3 formulas.

TITLE: The Influence of the Character of the Load on the Driving Function of an Electromechanical Amplifier

PERIODICAL: Izvestiya vyssikh uchebnykh zavedeniy, Elektromekhanika, 1959, Nr 5, pp 38 - 43 (USSR)

ABSTRACT: It is well known (Refs 1, 2 etc) that a rotating amplifier, on open circuit, can be represented by Eq (1) while the corresponding expression for purely resistive loading is Eq (1a). In Ref 2 a large number of frequency responses are presented in support of the validity of Eq (1a). If the behaviour with an inductive load is required, the driving function is most conveniently factored as in Appendix I using the frequency-dependent coefficient of Eq (4). The suitability of Eq (4) for design purposes is demonstrated in Figure 1 for an EMU-25 amplifier loaded with 22 ohms and 17 henry. The machine parameters are in Table 1. A better method of determining the

Card 1/3

SOV/144-59-5-5/14

The Influence of the Character of the Load on the Driving Function
of an Electromechanical Amplifier

essential parameters is that in Refs 3 and 4. If the amplifier is critically compensated and feeds an unloaded motor the amplifier becomes markedly under-compensated and can be considered as a simple-lag circuit with driving function of Eq (7). This result has been verified on EMU-5, EMU-50 and EMU-25. The results for the last case are in Figure 2. For comparison the ordinates of the frequency response are given in Table 2 both for the experimental case and according to Eqs (1a) and (7). It will be noted that the assumption made by several authors that a loaded amplifier can be represented by a simple-lag circuit is valid only for particular load and compensation conditions. Saturation in the magnetic circuit of the amplifier also has a significant effect on the frequency response. Figure 3 is an open-circuit response taken for different outlet voltages. The cut-off frequency and damping are both affected.

TITLE: Determination of transfer functions of elements from their frequency characteristics

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Elektromekhanika,
no. 10, 1961, 72-81

TEXT: The authors describe a new method of determining transfer functions of elements in the automatic control systems. The method consists in simultaneously taking the frequency characteristics of all elements, including the unknown element, in an open-loop control system set to operating conditions sufficiently close to the future real operating conditions. Subsequently, the transfer function for the unknown element is written in the generalized form:

$$w_{el}(p) = \frac{b_0 p^m + b_1 p^{m-1} + \dots + b_{m-1} p + b_m}{p^n (a_0 p^n + a_1 p^{n-1} + \dots + a_{n-1} p + a_n)}, \quad (2)$$

Title : Probable ionization of μ^- -mesons in g-s in the impulse range
between $4 \cdot 10^8$ and $1.2 \cdot 10^9$ cm/c

Periodical : Dok. AN SSSR 100/5, 883-886, Feb 11, 1955

Abstract : Experiments with relativistic μ^- mesons are described. The experiments were conducted for the purpose of ascertaining the effect of the velocities of μ^- mesons (of the energy range between $4 \cdot 10^8$ - $1.2 \cdot 10^9$ cm/c) on their ionizing characteristics. The experiments were conducted with the help of a 4-layer proportional counter and of a modern mass-spectrograph. Twelve references: 2 USA, 2 German, 3 British and 5 USSR (1932-1953). Graphs.

Vaynshteyn, Doctor of Technical Sciences, Professor I. A. Vinogradov, and G.M. Pobelitskova, Doctor, M.S. Z.I. Mamai.		
Comments: This volume is intended for scientists, engineers, physicians, and students of universities in the production and peaceful application of atomic energy, for professionals and specialists who work in atomic energy, students of schools of engineering, technical universities, where the subject is taught; and for people engaged in atomic activities.		
This is volume 3 of a two-volume set of reports on atomic energy, prepared by Soviet scientists at the Second International Conference on the Peaceful Uses of Atomic Energy, held in Geneva from September 1 to 13, 1955. Volume 1 consists of two parts. The first part, edited by A.I. Bokharev, is devoted to geometry, prospecting, concentration and processing of nuclear materials, metallurgy, and technology of nuclear fuels and reactors. The second part, edited by G.I. Zverev, includes 27 reports on neutron, neutron-irradiation effects on metals. The titles of the individual papers in most cases correspond word for word with those in the original Russian language edition on the Conference proceedings. See also/2001 for the titles of the other volumes of this set.		
Editor: A.I. Bokharev, G.D. Tsvetkov, G.D. Glushkov, I.P. Tolokonnikov, and N.S. Slobodchikov. Participants: International Association of Hydrocarbon Deposits of the Soviet Union (Report No. 2201)

<p><i>Ca</i></p> <p>A study of the (electric) charge and a method of separating the colloidal fraction of the soil by means of cataphoresis. V. Kovda. <i>State Inst. Tobacco Investigations (U. S. S. R.) Bull.</i> 78, 21-38(1931). Soil colloids from the different horizons of soils varying in reaction from pH 9.4 (a solonetz) to 5.4 (podsol) were tested for their charge by means of cataphoresis and they were all found to be neg. A special cataphoresis cell was built for the separ. of the colloids in suspension in the anode chamber. Twenty-five g. of the soil was boiled for 1 hr. in 100 cc. of water under reflux. The suspension was dild. to 800 cc. in a 30-cm. cylinder. After 90 hrs. standing the 28-cm. layer was pipetted off and transferred to the cathode chamber. Both the suspension and migrated colloids were evapd., the dry wt. and wt. after ignition detd., and the residue was fused and analyzed. For the transfer of the particles which were of a size smaller than 0.00096 mm. a voltage of 110-20 was maintained. After 40 hours the anode chamber with the migrated particles was removed and another chamber introduced and the cataphoretic movement continued for 40 hrs. more. Usually a settling of the particles in the anode chamber could be noticed 10-18 min. after closing the circuit. Analyses were made on the migrated particles from the 1st and 2nd 40-hr. periods. Tables and graphs are included. The alluvial horizon of a podsol gave 3.7 g. of colloids, of a solonetz 1.1 g. and of a chestnut soil 0.61 g. The chivial horizons of the corresponding soils, after 80 hrs. cataphoretic movement, gave: 0.44 g., 0.11 g., 0.27 g. and of the terra rossa only 0.09 g. The chief component of the colloidal fraction of all the various suspensions was SiO_2 (67-46%), followed by MgO (17-36%) and org. matter together with water of hydration (about 12-41%).</p> <p>J. S. The types of alkali soils (solonetz), V. A. Kavala, *Geog. rev., Acad. sci. U. R. S. S. [N. S.]*, 3, 207 (1938).—The factors which control the conversion of solonchak soils into solonetz and their further evolution are: lowering of the erosion level of poorly drained soils by relative elevation; entrance into a period of normal erosion; development and deepening of stream valleys and development of drainage relations; lowering of the ground-water level, thus lessening its influence; increasing importance of downward-flowing solins; and finally, removal of the salt. The reaction between Na_2CO_3 and CaSO_4 plays a part here. The principal forms of the alkali soils which represent successive stages of their evolution are solonchak solonetz, residual solonchak solonetz, gypsum-free solonetz, sodium-alkali soils and sodium solonetz solonchaks. The properties of each of these and the mechanism of their formation are discussed.

PROPERTIES AND PROBLEMS OF SOILS

Mineralization of saline soils by means of thermal dehydration of its colloids. V. A. Kovda. *Colloid J.* (U. S. S. R.) 4, 43-53 (1938). Heating saline soils for a short period at 70°, 100° and 150°, also in a muffle furnace at 300-550°, resulted in fundamental changes in all the specific saline properties of soils. The max. changes occurred in samples heated at 300-500°. The higher temp. treatment imparts to the soil a neutral reaction without lossing its cationic capacity, and a granular structure stable in H₂O and, therefore, better filtering properties. The adsorbed Na becomes unexchangeable. Destruction of saline properties on heating is due to dehydration of gels and minerals of the montmorillonite group which leads to crystn. of the gels and to a greater packing of the mol. layers in the minerals. The result is a greater fixation of the cations and an inability of the soil to swell and disaggregate. Optimal heating temp. in most cases was 150-300°. In applying this method to the amelioration of saline soils the plowed up field is covered with chopped straw or weeds soaked in gasoline and a flame is applied. Another method consists in using firing machines ordinarily used in road construction. S. L. Madorsky

E-Z CARD

E-Z CARD

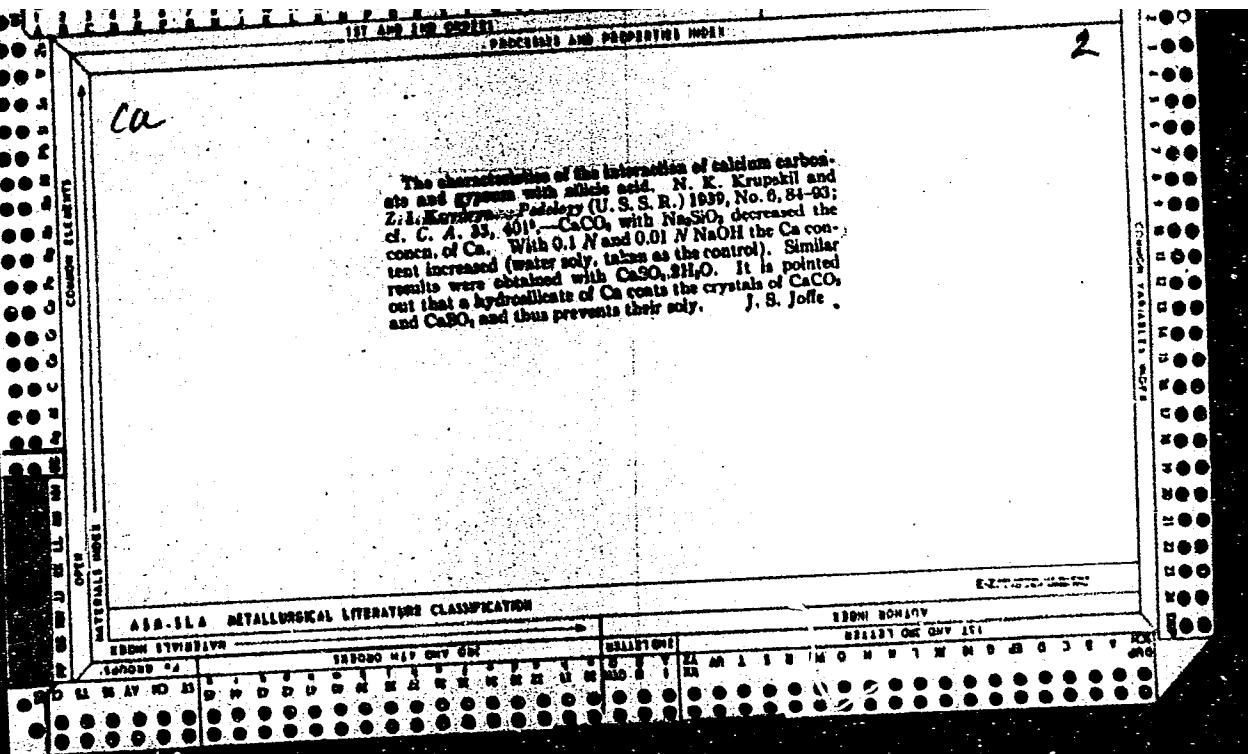

The solonetz soils. V. A. Kovda. *Pochvy S. S. S. R.* Akad. Nauk. S. S. S. R.; Pochvovedst. i. Dokuchaev. 1, 200 (1930); *Khim. Referat. Zhur.* 1939, No. 10, 39. Solonetz soils are formed by the removal of salts from the Na saline soils. The soil colloids (soil, with Na) cause an alk. reaction in the soil horzn. (pH 8.0-8.6). They become hydrophilic. In the saline horizon a process of soda formation takes place: soil Na + H₂CO₃ → soil H + NaHCO₃ and 2Na + Ca(HCO₃)₂ → soil Ca + 2NaHCO₃. The salt formation leads to a salin. with soda of the saline horizon and, in time, of the ground waters. The accumulation of soda in the free state is possible only in the later stages of the development of the saline process because gypsum inhibits the formation of free soda. The mineral part of the soil is decompd. in the eluvial horizon. The leivation of the eluvial horizon can be expressed by the following series of increasing mobility and lixiviation velocity of the compds.: Mn, P, Ti, Al, Fe, Mg, Si and Ca. Mineral and org. compds. accumulate in the eluvial horizon. The degree of accumulation can be expressed by the following ascending series: Mn, Si, Ca, Al and Fe. In the saline solonetz soils a progressive formation of salt in the upper horizons takes place simultaneously with the removal of salts from the profile; in the modifying solonetz soils salts are removed, the solonetz properties are lost and the properties of steppe soils increase; in the regraded solonetz soils the salt content is restored and the solonetz properties are lost.

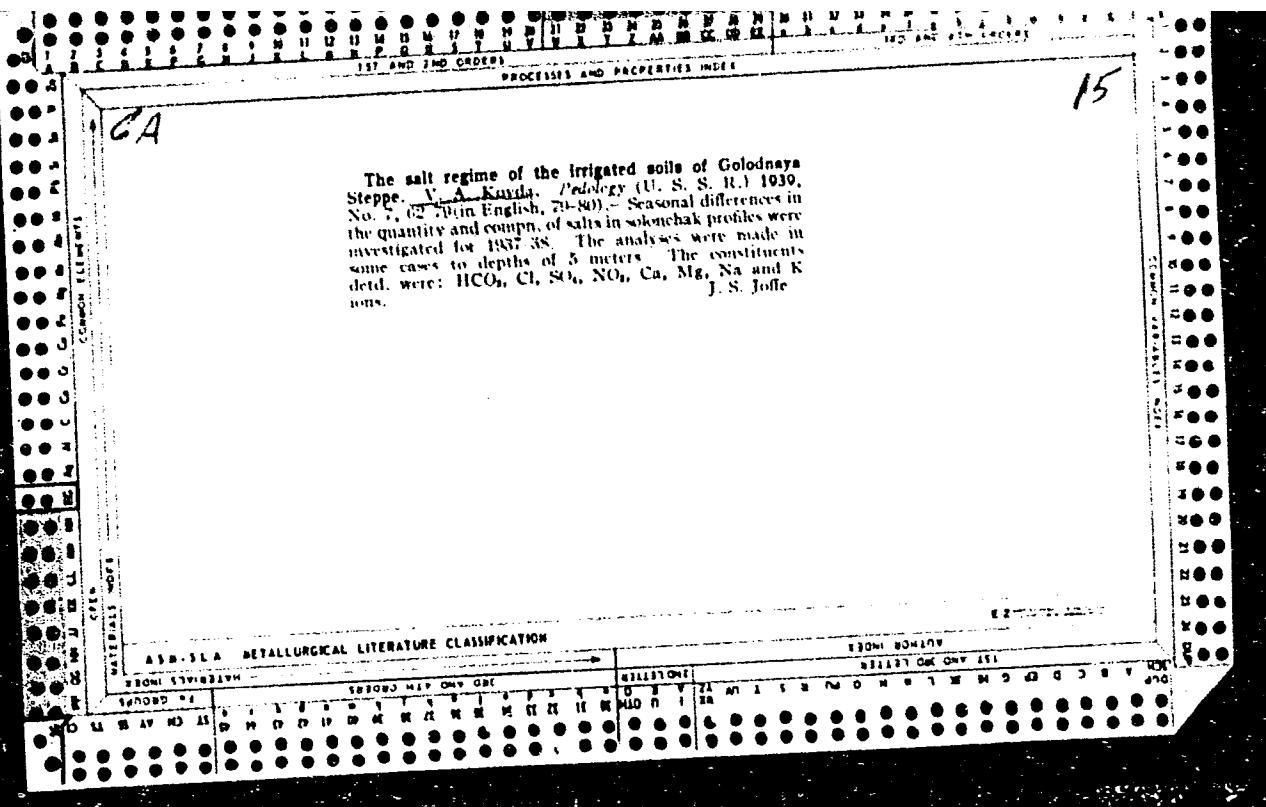

W. R. Henn

Salinity limits of the Pashin-Aral State Farm (Sakhalin) salt affects the texture and growth of cotton. V. A. Arshinov and L. J. Shishkova (Gidrogeologiya, 1959, No. 4, 50-56). Limits of salt content of irrigation water tolerated by cotton to lucerne and cotton plants of germination and later are stated with some inaccuracies. Salt resistance of both plants is similar. Cotton withstands which the growth had been adversely affected by salt containing more Mg, SiO ₂ , and Cl, and less Na and Fe (and possibly Mn), than normal. It is suggested that the depressed development of cotton on solonchak soils is due to Ca, Fe, and apparently Mn de- ficiency, as well as to poisoning by MgCl ₂ , S, and F. The total composition of the colloidal fraction in the Trans-Volga solonetz soils. V. A. Koyda and G. M. Kader. *Problemy Sovet. Pochvovedeniya* 1939, No. 7, 177-208; *Khim. Referat. Zhur.* 1940, No. 1, 70.—On the basis of a large no. of analytical data the following conclusions are made. The yield of colloids reaches 25%. The various components of the colloids are given by the following series $\text{SiO}_2 > \text{Al}_2\text{O}_3 > \text{Fe}_2\text{O}_3 > \text{MgO}$. The mol. ratio $\text{SiO}_2:\text{Al}_2\text{O}_3$ in the colloids is 4-5:1. The compn. of colloids in the solonetz soils differs from that of podzol and red soils. The yields of various oxides from the eluvial and illuvial horizons are represented by the series $\text{Al}_2\text{O}_3 > \text{SiO}_2 > \text{Fe}_2\text{O}_3 > \text{MgO}$. The order of ability of various oxides to be transformed into the colloidal state is $\text{Fe}_2\text{O}_3 > \text{Al}_2\text{O}_3 > \text{MgO} > \text{SiO}_2$. SiO_2 , Al_2O_3 , Fe_2O_3 , MgO and humus take part in the formation of the compact illuvial horizon in solonetz soils. There is a max. accumulation of Al_2O_3 in illuvial horizons of solonetz soils followed by SiO_2 and MgO .

ASA-SEA METALLURGICAL LITERATURE CLASSIFICATION

CA
"Limits of toxicity of salts in the Pakhta-Aral (Golodnaya Steppe) soils for alfalfa and cotton plants." V. A. Koyda and I. Ya. Mamayev. *Urologiya (U.S.S.R.)* 1970, No. 11, 30-31, 36-38. Akad. Nauk KazSSR, 1970, No. 11, 30-31, 36-38. Koyda and Mamayev determined the composition of the soils in arid areas and calculated the conditional content of ions per liter of the soil liquid from the wt. percentage of the solid residue, from the character of the ions and from the moisture content of the soils at the time of sampling. The conditional content is a definite water-salt coefficient that defines the character of the growth of plants. The analytical results are tabulated. Large amounts of salts have a harmful effect on the plants.

The movement and accumulation of silica in saltinized soils. V. A. Koyula. Trans. Dokuchaev Soil Inst. (U. S. S. R.) 22, No. 1, 3-27 (in English, 28-0) (1940).—K. shows, on the basis of a review of the literature and his own expts., that SiO_4 ions are carried in the profile of saline soils and upon reacting with $\text{CaSO}_4 \cdot 2\text{H}_2\text{O}$ and H_2CO_3 , the SiO_4 is released as an amorphous gel and then crystallizes as quartz. J. S. Joffe.

PROGRESSIVE AND PROPERTIES INVEST

The dynamics of alkalinity in soil solution upon irrigation V. A. Kudva, P. I. Shavrygin and T. A. Gavrilova, *Izdatelstvo TGU, S. S. R.* 1944, No. 2-3, 65-71 (in English, 71).—Sobouchak (sulfate and chloride-sulfate types) upon irrigation becomes more alk., all through the profile. The highest increase in pH takes place in the surface horizon. These increases in alk. are deleterious to cotton. By increasing the quantity of irrigation water it is possible to overcome the difficulty. A better method of handling these soils is to leach the salts before planting. L. S. Tolle

Types and stages of salinization of irrigated soils and measures to be taken in order to control it. V. A. Kovda, *Chernozem, acid, etc.* U.R.S.S. 49, 369 (1953) (in English). Four types of salinization in increasing order

of severity are recognized: (1) seasonal salinization of soils in summer because of insufficient watering, excessive evaporation, or poor crop development; (2) continuous spotty salinization because of uneven distribution of salts; (3) continuous salinization associated with ground water's containing 10-12 g. salts per liter; and (4) the same with 15-30 g. salts per liter. Control depends on adequate watering, drainage, mechanized tillage, and crop rotation involving alfalfa.

The process of salt accumulation (halogenesis) in soils and waters. V. A. Kovda. *Izdatelstvo (U.S.S.R.)* 1947, 078-0. — The present-day salt accumulation is a process composed of 3 branches: salt accumulation in ground waters, in soil soln., and in the solid phase of the soil. The max. limits of salt accumulation in the ground waters depend on the climatic conditions. In Siberia the limit is 40-60 g. per l.; in the lower Volga, 100-150 g./l.; in Uzbekistan, Tadzhikistan, and Azerbaijan, 200-220 g./l. The accumulation of NaCl in ground waters follows the equation $y = \beta_0 x$, where y = milliequiv. Cl, x = g./l. of residual solids; β_0 varies from 11 to 14. The accumulation of sulfate follows a more complex equation. At small concns., the accumulation follows a parabolic equation: $y' = \sqrt{2\beta_0 x}$, where y' = concn. of SO₄ in milliequiv., x = residual solids. At higher concns., the accumulation of SO₄ in ground waters does not take place, and the concn. of SO₄ is expressed by the equation $y = N$, where N values vary from 12 to 800. The relation of the concn. of salts in the ground waters to that of the soil soln. is discussed, with reference to seasonal variations, depth of water table, meteorologic conditions, and concn. of salts in water. It is pointed out that the max. concn. of salts in the soil soln. is 300-400 g./l. J. S. J.
