AUTHOR: Kurditskaya, A.A.

TITLE: Some peculiarities of surface seismic waves

PERIODICAL: Referativnyy zhurnal. Geofizika, no. 7, 1961, 12-13, abstract 7A12<sup>4</sup>  
(Tr. In-ta fiz. i geofiz. AN TurkmenSSR, 1959, v. 6, 108 - 119)

TEXT: The author analyzed recordings of surface waves from earthquakes in Greece on August 11, 1953, obtained at 5 seismograph USSR stations, which are located at different epicentral distances and azimuths in respect to the epicenter. The first stage of studying the nature of waves consisted in the plotting of spatial trajectories of the movement of ground particles in 30-minute intervals of the passage of a train of long-period oscillations. Further analyses were made of recorded sections which are characterized by elliptic trajectories, polarized in vertical planes. For the purpose of singling out Rayleigh waves, the author studied the distribution of azimuths of vertical planes in respect to their direction towards the epicenter, phase and amplitude correlations of vertical and horizontal components and their changes in time. It was established that the oscillations analyzed were in all cases interference oscillations, and

were formed by the superposition of Love and Rayleigh waves. This explains continuous changes in the orientation of the vertical polarization plane, in the shape and direction of the particle movement trajectory observed during the passage of surface waves. Azimuths of polarization planes in respect to the direction toward the epicenter for waves which are most similar to Rayleigh waves, are confined in a  $30 - 40^\circ$  wide sector; phase shifts of the horizontal and vertical component are mostly  $\pi/4$ . *44*

"Problem of the Study of Minimum Runoff of Small Rivers"  
Meteorol. i gidrologiya, No 1, 1954, 26-29

The method of computation of minimum runoff of small rivers in the absence or insufficiency of data is based mainly on the theory of minimum runoff proposed by N. P. Chebotarev ("Theory and Method of Determining Minimum Runoff, "authors' abstracts of reports at the scientific session of Voronezh University, 1950). Preceding from an analysis of the system isochrons of "reaching" [dobeganiye] of riverbed runoff, the author obtains  $Q_{\min} = 1000W(\bar{x}-\bar{p})$ , where  $Q_{\min}$  is the minimum discharge in the closing line of direction,  $W$  is the area of mirror of river system up to this line of direction,  $\bar{x}$  is the mean intensity of discharge of underground waters into the river, and  $\bar{p}$  is the mean intensity of losses (in summer from evaporation, in winter from ice formation) per unit area of the surface of the mirror per second. TITLE: On the Computation Formulae for Minimum Effluence (O formulakh dlya rascheta minimal'nogo stoka)

PERIODICAL: Meteorologiya i Gidrologiya, 1958, Nr 4, pp 36 - 38 (USSR)

ABSTRACT: In this paper (printed in the part "Discussion Questions" of the periodical "Meteorologiya i Gidrologiya") the author criticizes the formulae by N. D. Antonov (Ref 1) for the purpose mentioned in the title, which for the European part of the USSR are the most widely used ones. Antonov obtained 3 resembling formulae in the final result: For the summer-, winter- and month-average-minimum. No objections can be made against the structure of the formulae as a difference of two terms, further with regard to the inclusion of the necessary parameters into the second part of these formulae, which characterize the loss of the effluence for ice-formation and evaporation. In the second term of the mentioned formulae, however, the direct proportionality of the effluence-loss-modulus with the quantity  $M_0$  is by no means obvious in the same degree as it is the case in the first

Card 1/2

On the Computation Formulae for Minimum Effluence

50-58-4-13/26

term and this must be proved. At examples the author proves that the relation between  $M_p$  and  $M_e$  is not strictly proportional, as it appears from the formulae by Antonov. All this indicates that the second term of the empirically derived formulae by Antonov has no definite physical meaning, because the water losses in the formation of the effluence-minima are not in a direct relationship with  $M_e$ , as it appears from the Antonov formulae. Rather a very low inverse dependence or, at best, no relation at all exists. There are 7 references, all of which are Soviet.

Title : Interrelation Between the Oesophagus and Pleura

Orig Pub : Tr. Kafedry operativn. Khirurgii i topogr. anatomii.  
Tbilissk. med. in-t, 1956, 1, 29-33

Abstract : It was demonstrated on 77 human cadavers that above the root of the right lung the oesophagus (O) is covered in 53.2% of cases by the mediastinal pleura (MP) in the form of a band 0.1 - 0.6 cm wide; less frequently, the pleural sheet extends between the spine and the trachea, but does not reach the O (27.3%) or is separated from the O by a thick layer of connective tissue (16.9%). On the left, the MP usually covers the anterolateral surface of O

Card 1/2

Digestive System.

3

Abs Jour : Ref Zhur - Biologiya, № 2, 1958, №. 40714

with a band 0.4 - 1.5 cm wide (68.8%); less frequently, the MP is separated from the O (28.6%). Below the root of the right lung the MP either covers the edge of O with a band 0.2 - 0.4 cm wide (37.7%), or fully covers the posterior surface of O (36.4%), or else covers the right half of the posterior surface of O with a band 0.4 - 0.5 cm wide (25.9%). On the left, the MP passes over the O from the left anterior surface of the descending aorta, and covers it in the form of a distally widening band.

Title : On the Problem of Variability of the Form and  
Diameter of the Lumen of the Oesophagus

Orig Pub : Tr. Kafedry operativn. khirurgii i topogr. anatomii.  
Tbilissk. med. in-t, 1956, 1, 35-39

Abstract : The lumen of the oesophagus ( $O$ ) was measured in seven  
places on 91 human cadavers. It was demonstrated that  
the dorsoventral diameter of the lumen for the whole  
length of  $O$  is considerably smaller than the transverse  
diameter. The flattening of  $O$  is more pronounced in its  
upper half than in the lower. The oesophagus is  
collapsed above the point of division of the trachea;

Card 1/2

USSR / Human and Animal Morphology (Normal and Pathological).  
Digestive System.

S

Abs Jour : Ref Zhur - Biologiya, No 9, 1958, No. 40713

below this point the lumen of O is usually open,  
acquiring a form close to roundness as it approaches  
the diaphragmatic opening. No aortic and bronchial  
narrowings of O are noted on cadavers, although flexions  
of its wall at those levels were observed.

USSR / Human and Animal Morphology (Normal and Pathological).  
Digestive System.

S

Abs Jour : Ref Zhur - Biologiya, No 9, 1958, No. 40722

medially open angle (27.2%); usually, it is situated on the anterior surface of the kidney (86.4%). The transverse colon has the form of an arc with the convexity directed downward (54.4%), and lies horizontally (23.2%) or else has the appearance of an arc with the convexity directed upwards (16.6%); more frequently it does not form any loops (53.6%). The descending colon may have the form of a vertical tube (43.2%); less frequently it is directed downwards obliquely (29.6%). The sigmoid usually forms loops and either entirely lies in the pelvic area (54.5%), or rises into the abdominal area (46.4%).

Title : On the Problem of Variations of the Form of the Posterior Wall of the Mediastinum

Orig Pub : Tr. In-t eksperim. morfol. AN GruzSSR, 1957, 6, 205-210

Abstract : It was demonstrated on 77 cadavers of men that the line of transition of the thoracic pleura into the mediastinal, defining laterally the posterior wall of the mediastinum, is asymmetrical. On the right, this line, in 35.1% of cases, runs from the level of the head of the first rib obliquely down and medially; in 32.4% it passes onto the anterolateral surface, and in 29.4% on the lateral surface

Card 1/2

3

Abs Jour : Ref Zhur - Biologiya, No 9, 1958, No. 40, 61

of the I - III thoracic vertebrae. On the left, in 45.5% of cases it runs obliquely downwards and passes on the anterolateral surface of the II - III thoracic vertebrae, and in 42.8% it reaches the lateral surface of the II thoracic vertebra. Also variable is the direction of the delimiting line of the posterior wall of the mediastinum below the arch of the azygos vein and the aortic arch. In relation with this, the posterior wall of the mediastinum is in some cases represented by two distinct areas, and in others by one continuous area.

Title : Mutual Relationship between the Esophagus and  
the Vagus Nerves.

Orig Pub: Sabchota meditsina, 1957, No 2, 17-19.

Abstract: The author mentions that the accepted division of  
the esophageal plexuses of the nervus vagus (NV)  
into merely the simple and complex ones is not  
entirely accurate. It is shown that the main  
branches of the NV are joined to one another by  
single anastomoses on the anterior surface of the  
esophagus (E) in 30.6 per cent of cases, on the  
rear - in 38.7%. In other cases, the NV produce

Card 1/2

USSR / Human and Animal Morphology. Nervous System. S-2  
Peripheral Nervous System.

Abs Jour: Ref Zhur-Biol., No 14, 1958, 64795.

Abstract: one to two branches to the anterior surface (55%) or rear surface of the E (50.5%), or else send out to E two to three branches. Sometimes, on one of the surfaces of the E (on the anterior - in 14.4 and the rear - in 10.8 p.c. of the cases), there are 3-5 branches of the NV and a large number of anastomoses, in which case it is possible to speak of a nerve plexus. The branches of the NV and the anastomoses within the E unite into one to four trunks. One trunk forms on the anterior surface of the E in 78.9% of the cases, on the rear - in 67.6% of the cases. Less frequently two trunks are formed; quite rarely, their number is greater. One must distinguish not only the simple and the complex forms of the esophageal plexus of NV, but also several transitional forms.

Title : On the Problem of the Changeability of Esophageal Direction.

Orig Pub : Tr. Tbilissk. med. in-ta, 1957, 13, 55-67

Abstract : From the author's data (111 cases), 4 curvatures of the esophagus (E) were discovered: upper frontal (UFC) and sagittal (USC) are located above the aortic arch; lower frontal (LFC) and sagittal (LSC), below it. UFC in 85.6% of cases is turned by its convexity to the left; in 2.7%, to the right. In 11.7% UFC is absent. In 31.6%

Card 1/2

USSR / Human and Animal Morphology (Normal and Pathological). Digestive System.

S

Abs Jour : Ref. Zhur - Biologiya, No. 3, 1959, 12277

it starts on the level of the VIIth cervical vertebra; in 29.7%, on the level of the 1st thoracic. The level of the beginning of UFC with aging is transposed caudally not only in children but also in adults; in females this level is frequently higher than in males. LFC was discovered in 95.5% of cases; its beginning was located on the level of the VIIIth thoracic (36%) or IXth thoracic vertebra (29.7%). USC was constantly observed. LSC was also always expressed and started on the level of the bifurcation of the trachea; the maximum distance of E from the vertebral column was noted near the site of E passage through the diaphragm.

Orig Pub : Cement. Wapno. Gips, 1957, 13, No 5, 93-100

Abstract : Experiments were carried out on determination of hydraulic activity of granulated blast-furnace slag (S) by means of differential thermal analysis (DTA). Some samples were investigated in addition by the x-ray procedure in order to determine changes in the structure of S after the heat treatment. The results thus obtained show that the DTA method permits an accelerated determination of hydraulic activity of S and makes it possible to ascertain empirical correlations between surface effect and strength

Title: Influence of the Drying Temperature of Slag on the Properties of  
Slag Cements

Original  
Periodical: Cement. Wapno. Gips., 1954, Vol 19, No 8-9, 201-207; Polish

Abstract: The effect of the chemical and mineral composition and structure of blast furnace slag on its properties has been investigated. When granulated blast furnace slag is heated to high temperatures during drying devitrification may set in, since under those conditions crystallization centers can be created and existing crystallization zones can be extended. Such changes lead to a modification of the physical properties of the slag. In order to establish the "critical" drying temperature for the slag, a number of experiments were carried out in

Abst Journal: Referat Zhur - Khimiya, No 1, 1957, 1687

Abstract: which slag samples containing up to 31.27% moisture were placed in metal containers 40 x 15 x 4 cm with perforated bottoms and heated to 150-800° in a laboratory oven; after soaking for the prescribed time at maximum temperature the samples were cooled. The products obtained were investigated by the following methods: (1) blast furnace slag cements were prepared from the dried slag (with addition of portland cement clinker) and tested for tensile and compressive strength; (2) powdered samples of the slag were analyzed with a petrographic microscope; (3) differential thermal analyses were made on the slag. Blast furnace slag cement samples prepared from slag dried at 400° showed the highest compressive strength. Good compressive strength values were obtained with slag dried at 150-600°. Heating the slag to 700 and 800° considerably decreased the strength of the samples; this is apparently due to changes in the physical properties of the slag (devitrification). Soaking the slag at 150° leads to an increase in strength as the soaking time was increased to 17 hours; a rapid increase in strength was observed as the soaking time was increased up to 5 hours, after which the strength increased rather

**Abstract:** slowly. At 400° maximum strength was attained after soaking for 3 hours; a further increase in soaking time decreases the strength of the samples (particularly the compressive strength). The best tensile strength values were obtained when the slag was soaked 5 and 17 hours at 150°. A marked decrease in the hydraulic properties of the slag when cement samples produced from the latter are heated during the tensile strength test was observed only at 800°. The microscopic examination of heat-treated slag samples showed the presence of a fairly large amount of individual crystals. However, no significant difference in the crystalline content of heat-treated slag compared to air-dried slag could be observed. Compressive strength measurements and differential thermal analysis showed that devitrification of the slag sets in at temperatures above 700°. Hence temperatures over 700° must be avoided in the commercial drying of slags since they cause a reduction in the hydraulic properties of the slags.

TITLE: Lignin as a Reinforcing Agent of SKS-30 Rubber

PERIODICAL: Kolloidnyy zhurnal, 1959, Vol XXI, Nr 5, pp 306-308  
(USSR)

ABSTRACT: The authors report on a study of the properties of vulcanizates, each containing a variety of activated lignin. The lignin varieties used for the experiments were powdered and ground with the vibromill, chloro- and alkali-activated. Vulcanizates containing alkali-activated lignin were mostly reinforced. Electron microscopic investigation revealed that coagulation of alkali-activated lignin results in the formation of a reticular structure, which is similar to the structure of carbon black. This structure, which could not be seen in the other varieties, evidently accounts for the reinforcing effect of alkali-activated lignin. The authors mention the Soviet scientists N.N. Shory-

gina, S.I. Sukhanovskiy and M.I. Chudakov, who developed methods to activate lignin obtained by hydrolysis. They further refer to E.L. Morgulis, who investigated the dispersing effect of mechanical forces during the processing of lignin in vibromills. There are 6 electron microscopic photographs and 7 references, 6 of which are Soviet and 1 English.

TITLE: Possible utilisation of cadaver bone marrow in a clinic

TRANSLATION: A method of taking bone marrow from cadavers for

or bone marrow obtained increased if the cadavers were preserved at  
for 15 days following human death. In this investigation the number of megakaryocytes, myeloma-  
cytes, mitoses, and the degree of stain changes were determined

ACQUISITION FILE: AR4039975

for RNA, DNA, and glycogen. Morphological change and destruction of bone marrow cells took place by the 3rd day. Only lymphocytes and some of baso- and oxyphile erythroblasts were preserved in vivo on the 6th day. Twenty-one patients were examined.
