to the Editor

77253  
SOV/89-8-2-18/30

Equation (3) holds for an object of infinite length and is also good for bounded geometry to approximately 10% accuracy. The authors computed the dose field for  $\text{Co}^{60}$  rays. Absorber was water, and values of constants used in the computation of Fig. 2 were:  $\mu = 0.063 \text{ cm}^{-1}$ ;  $a_1 = -0.095$ ;  $a_2 = 0.060$ ;  $A_1 = 8.88$ ;  $A_2 = 1 - A_1 = -7.88$ . To find from this picture the dose in air at a point A, one has to use the curve  $\Sigma = 0$ . An approximate formula accurate to 10-15% is:

$$P_A = P_0 e^{-\mu(h - \Delta)}, \quad (6)$$

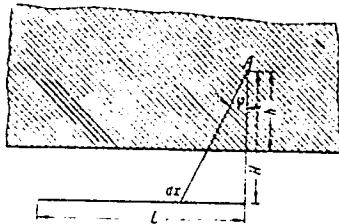

where  $P_0$  is dose strength in air at the given point, and  $\mu$  and  $\Delta$  are constants, depending on ratio  $H/L$ . This formula works for cases  $h \geq 10 \text{ cm}$ , at  $H/L \leq 0.1$ ; for  $h \geq 15 \text{ cm}$ , at  $0.6 \geq H/L \geq 0.2$ ; and for  $h \geq 20 \text{ cm}$ ,

SOV/89-8-2-18/30

where  $\Phi_0 = \tan^{-1} \frac{h}{H}$ ; H is distance from point A to the source;  $k_\gamma$ ,  $\gamma$ -constant of the isotrope; m, linear activity of the source in  $\mu$  Curie/cm (if m is expressed in mg equivalent Ra, then  $k_\gamma = 8.4 \text{ R/h} = 0.14 \text{ R/min}$ );  $\mu$ , linear coefficient of decrease of a thin beam of  $\gamma$ -rays;  $A_2 = 1 - A_1$ , a constant;  $A_1$  and  $A_2$ , constants whose values for various absorbers and various energies of radiation are given in Goldstein's report and Rockwell's book (see refs).

AUTHORS: Grammatikati, V. S., Margulis, U. Ya., Khrushchev, T. G.

TITLE: The Dose Field of a Linear Source. Letter to the  
Editor

PERIODICAL: Atomnaya energiya, 1960, Vol 8, Nr 2, pp 154-155 (USSR)

ABSTRACT: Since radioactive line sources are fairly common in applied and experimental devices, the authors thought it useful to present an approximate but sufficiently accurate method of calculations. As is known, the dose strength  $P_A$  of point A at distance  $h$  inside an object, Fig. 1, can be represented by means of tabulated integrals of Sievert (see ref):

$$P_A = \frac{k_1 m}{H} \left[ A_1 \int_0^{q_0} r^{-\mu h (a_1 + 1) \sec q} d\Phi + A_2 \int_0^{q_1} r^{-\mu h (a_2 + 1) \sec q} d\Phi \right]. \quad (3)$$

PURPOSE : The publication is intended for scientific workers and specialists employed in enterprises where radioactive isotopes and nuclear radiation are used for research in chemical, geological, and technological fields.

COVERAGE: This collection of 133 articles represents the second volume of the Transactions of the Tashkent Conference on the Peaceful Uses of Atomic Energy. The individual articles deal with a wide range of problems in the field of nuclear radiation, including: production and chemical analysis of radioactive isotopes; investigation of the kinetics of chemical reactions by means of isotopes; application of spectral analysis for the manufacturing of radioactive preparations; radioactive methods for determining the content of elements in the rocks; and an analysis of methods for obtaining pure substances. Protection From X- and Gamma Rays

SOV/5330

The book focuses main attention on protection problems themselves, dealing in detail with the passage-mechanism of x-rays and  $\gamma$ -rays through matter, principles of design, and the properties of materials used for protection. Protective structures and installations are also described, and examples of design and design nomograms are given. There is also some information on the biological effects of radiation. The present work represents an attempt to collect, systematize, and present in detailed and orderly fashion the considerable number of articles on problems of radiation protection which have appeared in the periodical literature to date. The second edition is an improvement over the first edition, inasmuch as the material has been reworked and supplemented with new material, and some material of a general character has been eliminated. Ch. I to III and Section 4 of Ch. IV were written by U. Ya. Margulis; A. V. Bibergal' wrote Ch. IV (excepting Section IV), V, VI, and VII; Ye. I. Borob'yev wrote Ch. VIII; A. V. Bibergal' and U. Ya. Margulis selected and compiled the material for the appendices. There are 65 references: 38 Soviet (including 5 translations), 26 English, and 1 German.

807/589

*Soviet radiobiological I dosimetric methods (Collection of Radiochemical and Dosimetric Methods) Moscow, Nauka, 1959. 499 p. Printed slip inserted. 9,000 copies printed.*

*Ed.: (Title page): B.G. Omer, G.Ye. Margulis, A.I. Savchenko, M.N. Tsvetkov, V.I. Tabakov; Tech. Ed.: A.I. Tsvetkov.*

**PURPOSE:** This collection of articles is intended for physicians, sanitarians and public health doctors, chemists and other specialists working in radiobiology.

**CONTENTS:** This work discusses the following subjects: (1) principles of organizing sanitation and dosimetric control in institutions where work is carried on with radioactive substances; (2) radio-chemical methods for determining certain radioactive substances in samples of air, water, soil and foodstuffs; (3) physical methods of measuring concentration of the air by radioactive gases and aerosols, and methods for determining the level of ionizing radiation from working environment, objects and other sources; (4) methods of determining external sources of ionizing radiation, and methods of individual dosimetric monitoring; (5) absolute and relative methods of measuring the activity of solid and liquid radioactive sources. There are four appendices dealing with methods of calculating the total dosage from sources or locating radiation, units of activity, and doses from natural background radiation. In the calcium and foodstuff section, dietary regulations observed during transportation, storage, and handling of radioactive substances are discussed, as well as the permissible level of shielding radiation. Two tables taken from Soviet and U.S. literature. References appear at the end of each chapter.

PERIODICAL  
ABSTRACT

The authors of the paper under review describe an experimental arrangement for the sterilization of grain with the aid of the  $\gamma$ -radiation of  $\text{Co}^{60}$ . The radiation device has the shape of a hollow cylinder to the generatrix of which there are attached twenty radioactive bars of a total activity of 100,000 g equivalent radium. This device has water protection. The grain is automatically exposed to radiation. The operational capacity of the device amounts to 1.85 tons per hour. For the construction of industrial plants for the radioactive sterilization of grain the use of  $\text{Co}^{60}$  is uneconomical because of the high costs involved. Much more favorable is the utilization of fission products of uranium which are obtained from atomic industry. Because of the low specific activity of the fission products the selection of the most economical configuration of the radiation device is the most important problem. According to the computations, cellular (meshed) radiation devices are most favorable. The paper under review discusses three types of such cellular radiation devices, namely cylindrical, bar-shaped, and slot-shaped devices. According to the author of the paper, slot-shaped devices can be used most economically because they yield the highest output per unit volume of the device. The output of such a radiation device amounts to 31 tons per hour at a total activity of  $3.72 \cdot 10^6$  Curie. The relatively low

*Atomnyy vzryv i nekotoryye voprosy protivoatomnoy zashchity (Nuclear Explosion and Some Problems of Atomic Defense) Moscow, Medgiz, 1958.  
68 p. 100,000 copies printed.*

ED.: Miklashevskiy, V. Ye.; Tech. Ed.: Bul'dyayev, N. A.

PURPOSE: The pamphlet is intended to inform the general public of the characteristics of atomic bombs, to indicate the principal rules to be observed during an atomic attack and to point to possible defensive measures.

COVERAGE: The authors claim that in the Soviet Union the use of nuclear power is directed primarily towards constructive purposes, but so long as the use of atomic weapons is not prohibited and the danger of a new destructive war exists, effective measures must be undertaken in times of peace to meet the threat of a sudden atomic attack on large industrial centers. The authors assert that a widespread knowledge of the nature of an atomic war is of

TITLE: Computation and Measuring of the  $\gamma$ -Field of a Plane Source  
(Raschet i izmereniye  $\gamma$ -polya ot ploskogo istochnika)  
PERIODICAL: Atomnaya Energiya, 1957, Vol. 3, Nr 10, pp. 338-341 (USSR)  
ABSTRACT: The equations for the calculation of the dose of a plane source are derived theoretically and herefrom the isodose curves are formed. Further, measuring of the dose on a quasi-plane source (11 adjoining, active rods of a length of 1 m) are described with 418 mC. As the quintessence of all deliberations it is shown that an apparatus with a source consisting of 2 parallel plates with a distance of 25,44 cm and a total activity of  $Q = 1000$  milligram - radium equivalent possesses an efficiency of 35,616 kg, where in the center of both plates there is a dose of 0,21 r/min. If, however, an apparatus is used for which an equivalent, cylindrical source of equal strength is used (d. 25,44 cm, length 100 cm), then only an efficiency of 16,18 kg exists, where, however, in the center of the source, there is a dose of 0,291 r/min. There are 7 figures.

AUTHOR APPROVED FOR RELEASE 06/20/2000 BY PERTSOVSKY E.S. PA - 2727  
TITLE Use of Strong Radiation Sources for the Sterilization of Grain PA - 2727  
(Izpol'zovaniye moshchnykh istochnikov izlucheniya dlya obezzaryazh-  
eniya zerna /Russian).  
PERIODICAL Atomskaia Energiia, 1957, Vol 2, Nr 4, pp 376-384, (U.S.S.R.)  
ABSTRACT The authors of the paper under review describe an experimental arrangement for the sterilization of grain with the aid of the  $\gamma$ -radiation of  $\text{Co}^{60}$ . The radiation device has the shape of a hollow cylinder to the generatrix of which there are attached twenty radioactive bars of a total activity of 100,000 g equivalent radium. This device has water protection. The grain is automatically exposed to radiation. The operational capacity of the device amounts to 1.85 tons per hour. For the construction of industrial plants for the radioactive sterilization of grain the use of  $\text{Co}^{60}$  is uneconomical because of the high costs involved. Much more favorable is the utilization of fission products of uranium which are obtained from atomic industry. Because of the low specific activity of the fission products the selection of the most economical configuration of the radiation device is the most important problem. According to the computations, cellular (meshed) radiation devices are most favorable. The paper under review discusses three types of such cellular radiation devices, namely cylindrical, bar-shaped, and slot-shaped devices. According to the author of the paper, slot-shaped devices can be used most economically because they yield the highest output per unit volume of the device. The output of such a radiation device amounts to 31 tons per hour at a total activity of  $3.72 \cdot 10^6$  Curie. The relatively low

TITLE: The Utilization of the Industrial Surroundings Found at a Boarding School in the Teaching of Physics (Ispol'zovaniye proizvodstvennogo okruzheniya shkoly-internata v prepodavanii fiziki)

PERIODICAL: Fizika v Shkole, 1958, Nr 3, pp 61 - 67 (USSR)

ABSTRACT: The author recommends the use of the industrial surroundings found at his boarding school for polytechnical instruction. The school has its own locksmith, carpenter and sewing workshops; laboratories; 10 ha of land; a DT-14 tractor and other agricultural machines; a GAZ-51 truck; a radio broadcasting and receiving unit; a motion picture installation of the type "Ukraina"; a photo laboratory and a weather bureau. The school has central heating, its own electric power plant, a mechanized laundry, a kitchen with electric wiring and refrigerators. The students have all these possibilities to study physics and to simultaneously observe its practical application. Moreover, the author points out the importance of excursions to neighboring industrial enterprises for the better understanding

cylindrical samples made by compacting powdered mixtures and firing them at 1700°C. Other tests were carried out with samples in the shape of crucibles, tips, or cubes made by casting or compacting (cubes), followed by firing at 1650—1750°C. The coefficient of thermal expansion of the  $\alpha$ -alumina (corundum)-base samples was significantly decreased; hence, the thermal stability was increased by increasing the aluminum titanate content. Microscopic phase analysis confirmed this finding. Great importance was attached to the fact that the thermal expansion in the 100—400°C range of the samples with 90% aluminum titanate, 9% alumina, and 1% aluminum phosphate was the same as in pure aluminum titanate. This was considered as an indication of the possibility of making other compositions of the three materials, which would have a zero or near-zero coefficient of thermal expansion in various temperature ranges up to 500°C. The tests of the corundum-base products showed that compositions with 20—25% aluminum titanate displayed high refractoriness (about 1930°C), good compressive strength at subzero temperatures, and high thermal stability in molten metals. The aluminum titanate-based products had also high compression strength at subzero temperatures and high thermal stability, including that in molten metals. Orig. art. has: 5 figures and 3 tables. TITLE: Properties of aluminum titanate- and alumina-base products

SOURCE: Ogneupory, no. 2, 1965, 23-27

TOPIC TAGS: refractory compound, alumina, corundum, aluminum titanate, refractory product, thermal property, mechanical property

ABSTRACT: A study has been made of the effect of aluminum titanate and aluminum phosphate additions on linear thermal expansion, porosity, compression strength, and thermal stability of pure alumina and alumina/products. The possibility was tested of making refractory products with low thermal expansion, a characteristic of aluminum titanate, and sufficiently high compression strength, which is low in pure aluminum titanate products. Aluminum titanate powder was synthesized from pure  $\alpha$ -alumina and titania, and mixed with pure alumina or  $Al_2O_3 + 1\% TiO_2$  in various ratios. Aluminum phosphate (0.5-5%) was added to some of the mixtures. The coefficient of thermal expansion (in the 20-1200°C range) and the phase composition were determined in

form of cubes with an edge length of 300 mm and prisms 140 mm long with a cross section of 15 x 8 mm and were annealed with the coverings. The article gives tables with the results of tests on volumetric weight, porosity, compression yield point at 1650°C, and bending strength at 1400°C. Analogous tests were made on coverings made of magnesium oxide. In this case, the test samples contained 96.7% magnesium oxide and 2.5% calcium oxide. Orig. art. has: 1 figure and 3 tables.

AUTHOR: Margulis, O.M.; Usatikov, I.F.

ORG: Ukrainian Research Institute for Refractories (Ukrainskiy nauchno-  
issledovatel'skiy institut ogneporov)

TITLE: Thermocouple coverings made of zirconium dioxide and magnesium  
oxide

SOURCE: Ogneupory, no. 12, 1965, 42-45

TOPIC TAGS: refractory oxide, zirconium compound, magnesium compound,  
thermocouple, high temperature material

ABSTRACT: Object of the work was the development of thermocouple coverings which can operate at temperatures of 1900 and 2400°C. The zirconium dioxide used had a content of zirconium dioxide plus hafnium dioxide not less than 96%, and was stabilized with calcium oxide in the form of chalk. To improve thermal stability, the thermocouple coverings were made of a mixture of the cubic (stabilized) and the monoclinic (unstabilized) forms. The best thermal stability was shown by coverings made of mixtures containing 40-50% fused monoclinic zirconium dioxide or 20-30% annealed zirconium dioxide. The coverings were poured into gypsum forms and were dried in the forms to a moisture content of 0.5 to 1.0%. They were then annealed under annealing conditions given in a table. To test the mechanical properties of the coverings, samples were prepared in the

Card 1/2

UDC: 666.76:536.532

ACCESSION NR: AP4042633

fired at 1600°C. The tensile strength of the dried samples was 59.5 g/sq.cm. Shear strength data showed that binders based on aluminophosphate cement, refractory corundum parts reliably to graphite even after a 15-hour firing in an electric furnace up to 2000°C. The effect of an aluminophosphate binder on the properties of corundum samples, using alumina mixed with 1% TiO<sub>2</sub>, was also studied and the compressive strength was determined at 300, 1200 and 1600°C. Aluminophosphate binders were found to promote sintering, increase the strength after drying and heat-resistance, and did not decrease the temperature of deformation. The increase in heat resistance is associated with a decrease in the thermal expansion coefficient and possibly with the presence of glassy films which absorb the stresses at sharply changing temperatures. Addition of 1% aluminum phosphate to the corundum mass improved sintering, thermal resistance and compressive strength, and decreased the coefficient of thermal expansion with the simultaneous retention of the main properties. The volatility of P<sub>2</sub>O<sub>5</sub> does not affect the serviceability of the products and cements. "Microscopic studies were carried out by N. V. Gul'ko." Orig. art. has: 3 tables.

TITLE: Use of aluminum phosphate as a binder for refractory corundum products and cements  
24-

SOURCE: Ogneupory\*, no. 7, 1964, 329-332

TOPIC TAGS: refractory material, aluminum phosphate, corundum, cement, binder, alumina bonding strength, shear strength, firing, phosphorus pentoxide, refractory cement

ABSTRACT: The possible use of aluminum phosphate as a binder for making corundum products, especially parts of thermocouples, and for cementing parts to graphite and to steel was investigated. An aluminophosphate bonding agent with  $\text{Al}_2\text{O}_3$ :  $\text{P}_2\text{O}_5=1:3.5$ , density 1.57 g/cc, was used. Storage in a closed vessel for a month did not affect this binder. The effect of particle size on the stability of the binder was measured with a photoelectric nephelometer. It was found that the filtrate of an aluminophosphate binder contained suspended particles with a size of 370-600  $\mu$ , most of them being 370-420  $\mu$ . An aluminophosphate binder (density 1.58 g/cc, viscosity 7.8 cp) mixed with finely ground alumina in a ratio of 1:1.3 (resulting density = 3.59 g/cc) was then used for cementing samples which were

No. 6). Both oxides were chemically analyzed and tested for porosity, compressive strength, and bending strength. Their heat absorption and their coefficients of heat conductivity and of thermal expansion were determined. The two materials were also checked for chemical interaction when in contact with each other for 40 minutes at 1800°C. These last tests proved that magnesium oxide should be separated from zirconium dioxide by gaskets of strontium zirconate or calcium zirconate. Thermal stability was studied at various rates of cooling, various lengths of heating-cooling cycles, and at velocities of gas flow up to 100 m/sec. In this work the sponge insulation rings, though resistant to heat, were found to suffer from erosion under the flow of hot gases. Rings made of magnesium oxide did not decrepitate even after 400 cycles in the 1900-1500°C heating-cooling range, but when using them the furnace lining had to be made of the same material. Sponge made of magnesium oxide was found inferior to that made of zirconium dioxide. The authors recommend that magnesium oxide be used for manufacturing objects subjected to temperature changes of 400°C for long periods and to changes of 900°C for shorter periods. N. V. Gul'ko performed the petrographic investigations. Orig. art. has: 2 photographs and 3 tables.

SOURCE: <sup>21</sup> Ogneupory\*, no. 5, 1964, 206-209

TOPIC TAGS: zirconium dioxide, magnesium oxide, thermal stability, refractory material, compressive strength, bending strength, heat exchange, heat insulation, corrosion resistance, erosion resistance

ABSTRACT: Objects made of zirconium dioxide and magnesium oxide were tested in temperatures up to 1900°C. Zirconium dioxide blocks (produced from molten material with an addition of 8% of CaO) were ground to  $2\mu$ , freed of iron, and mixed with monoclinic zirconium dioxide. Test specimens were pressed from material mixed with water-diluted molasses. Magnesium oxide briquettes (burned at 1750°C) were dry ground to  $10\mu$  and were processed as above. Experimental refractory columns were built up of rings 15 and 25 mm in external diameter and 10 mm high. Their wall thicknesses were 3, 3, and 2 mm. The specimens were held in rings 75 mm in diameter, 10 mm thick, and 26 mm high. Heat-insulating rings were prepared of zirconium dioxide sponge according to the method described by A. A. Pirogov (Ogneupory\*, 1962,

measuring temperatures in vacuum. When the thermocouples were placed near the water-cooled parts of the oven, their jackets were destroyed by the abrupt temperature differences. The MgO coverings can be used in taking measurements under argon at 2400°C for a period of 5 hours, while the ZrO<sub>2</sub> jackets withstand a temperature of 2400°C for several minutes and may be used for extended periods at 1900°C in vacuum, under nitrogen and under argon. The long coverings had to be attached to graphite supports to prevent their bending at high temperatures. Orig. art. has: 2 tables and 3 figures.

TITLE: Large items of high thermal stability made of zirconium dioxide

SOURCE: Ogneupory\*, no. 2, 1964, 63-67

TOPIC TAGS: zirconium dioxide, thermal stability, refractory characteristic, refractory material, refractory shape effect, refractory size effect

ABSTRACT: It was previously established that the thermal stability of refractory materials made of zirconium dioxide increased if certain amounts of isometric monoclinic ZrO<sub>2</sub> were melted and mixed together. The present work was carried out in order to determine the optimal quantities of the monoclinic part and the optimal grain sizes of both parts. The experiments showed that: 1) thermal stability of large items made of zirconium dioxide increased with the use of 0 to 60 μ fraction of isometric ZrO<sub>2</sub>; 2) the monoclinic zirconium (introduced in insignificant quantities) gave best results when its grain sizes were smaller than 2 μ but even with 60 - μ grains its thermal stability and the deformation temperature under load remained satisfactory; 3) 15% of coarse monoclinic zirconium gave the best results

TITLE: Refractory materials for the protection of thermocouples used in high-temperature measurements

SOURCE: Ogneupory\*, no. 1, 1964, 24-28

TOPIC TAGS: refractory material, zirconium dioxide, magnesium oxide, thermocouple protective jacket, VR 5/20 thermocouple, OPPIR-09 pyrometer; Tamman electrical oven, TVV-2M oven, high-temperature oven

ABSTRACT: A procedure for the production of thermocouple jackets is described. These jackets made of zirconium dioxide and magnesium oxide were up to 600 mm long and 22 mm in diameter. Despite the differences in their compositions, it has not been possible to determine which material is the more advantageous. The tests were carried out in a Tamman electrical oven, a TVV-2M oven, and in high-temperature ovens. It was established that thermocouple coverings described here should not be used under reducing conditions. Tests carried out at  $1 \times 10^{-3}$  mm Hg pressure under argon in a TVV-2M oven showed that the MgO jackets should not be used for

17K 206 (Sb. nauchn. tr. Ukr. n.-i. in-t ogneuporov, no. 4,  
1960, 50-62)

TEXT: The author presents several methods for determining the thermal stability of refractories from pure oxides. It is shown that the thermal stability of the products depends on their structure. Increased thermal stability is observed in refractories containing two or more types of crystals. The difference in the coefficients of thermal expansion of crystals results in the formation of microfissures, which allows the individual grains to expand more freely on heating. In addition, the extension of cracks is impeded. [Abstracter's note: Complete translation] X

Products of fused zirconium dioxide with high temperatures resistance

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 4, 1961, 6, abstract, 4B34  
("Sb. nauchn. tr. Ukr. n.-i. int ogneuporov, 1960, no. 3(50).  
153-171)

TEXT: A method of preparing crucibles and products presenting a far better thermal resistance usually out of  $ZrO_2$  has been developed. The augmentation of thermal resistance for the crucibles and sinterings of  $ZrO_2$  is not determined by the amelioration of stabilization of  $ZrO_2$  in cubic shape, but by the use of the mixture (1/1) of the cubic Z and the monoclinic modification of melted  $ZrO_2$ . A rapid rise of strength at high temperatures and a reduction of thermal dilatation affect positively the increase of thermal resistance of the latter. In this case, the microstructure and the thin crystalline structure are apparently of decisive significance. Petrographic and roentgenographic methods were used to establish the destabilization of the cubic form of  $ZrO_2$ .

Dense Products of Magnesium Oxide With Increased Thermal Stability

PERIODICAL:

Ogneupory, 1960, Nr 3, pp 132-137 (USSR)

ABSTRACT:

In this paper the authors describe an economic procedure for the manufacture of fully sintered products of magnesium oxide with admixtures and at practically attainable temperatures. Table 1 indicates the chemical composition of the initial raw material and of the admixtures. Tables 2-4 show the characteristics of the magnesium-oxide samples with admixtures burnt at 1750°. The preparation of raw materials is thoroughly described, and the method of Grebenyuk (UNIIO) is referred to. In conclusion, the authors state that a procedure was worked out for the manufacture of plates with a porosity of 1-3% made of magnesium oxide with spinel linkage. They offer increased stability and considerable durability at high temperatures and finely

given in the table and the typical cuts in figure 4. Conclusions: The increased thermal stability of terminal pieces of technical alumina is guaranteed by the presence of two corundum crystal types: fine isometric and coarse prismatic.

Further the technology of production of this corundum crystallization is given and recommended to all works producing refractories in order to supply metallurgical plants with suitable terminal pieces for thermocouples. There are 4 figures, 1 table, and 5 references, 4 of which are Soviet.

The Terminal Pieces of Immersion Thermocouples (Nakonechniki  
dlya termopar pogruzheniya)

PERIODICAL:

Ogneupory, 1959, Nr 4, pp 157-161 (USSR)

ABSTRACT:

Immersion thermocouples with terminal pieces of quartz can be used only one time up to a temperature of 1600°. The platinum-platinum-rhodium thermocouples are further rapidly worn out. In the Podol'sk plant of refractories experiments with terminal pieces of technical alumina are carried out, the technology devised by UNIIIO serving as a basis (Fig 1). A set of 500 terminal pieces was tested in the works "Elektrostal'" by representatives of manufacturers and consumers, of the Ukrainian and All-Union Institutes of Refractories, and the Tsentral'naya laboratoriya avtomatiki Ministerstva stroitel'stva RSFSR (Central Laboratory of Automation of the Ministry of Building of the RSFSR). The laboratory of the Podol'sk works performed petrographical investigations in which N. V. Gul'ko assisted (Ref 1, Figs 2 and 3). The influence of burning and of an addition of 1%  $TiO_2$  was investigated. The results are

Card 1/2

On the Destabilization of the Cubic Form of Zirconium Dioxide SOV/2o-121-3-35/47

MgO where the monocline  $ZrO_2$  modification was found (< 1%) was an exception. Thus the destabilization of the cubic form proceeds very slowly. The results are shown on tables 1 and 2. They reveal that the degree of decomposition of solid solutions  $CaO - ZrO_2$  and  $MgO - ZrO_2$  depends upon the composition of the additions and on the concentration of the solid solution. The thermal treatment (melting or sintering) has hardly any effect on the destabilization. The investigations carried out show how complicated the mechanism of decomposition of the mentioned solid solutions is and point to the need for further investigations. There are 2 tables and 12 references, 8 of which are Soviet.

Dioxide SOV/20-121-3-35/47

material from  $ZrO_2$ , it ought to be stabilized in cubic modification by various additions, which crystallize also in a cubic system. Furthermore, these additions ought to have a higher percentage of heteropolar bindings than  $ZrO_2$  itself (Refs 5). According to the latest papers this is true of CaO and MgO (Refs 5,7). Contrary to the leading opinions it was found that  $ZrO_2$  stabilized in the mentioned way is destabilized by heating for a long duration between 1100 and 1400° (Refs 5, 8,9). For the stabilization of  $ZrO_2$  the authors used 10 to 30 mol % CaO and 14 to 35 mol % MgO. The mixture was melted in the arc furnace and ceramically sintered in a forge with crude oil heating for 6 hours at a temperature of 1750°. It could be petrographically and roentgenologically proved that  $ZrO_2$  + CaO and MgO were represented in cubic form after both melting and sintering. After having been moistened with water a  $< 2\mu$  fine powder was pressed under a pressure of 600 kg/cm<sup>2</sup> into cubes and cylinders and baked at 1750° for 6 hours. In all cases the composition of the phases was microscopically determined to be cubic. The formula with 10 mol % CaO and 14 mol %

PERIODICAL:

Doklady Akademii nauk SSSR, Vol. 121, Nr 3,  
pp. 523 - 526 (USSR) 1958

ABSTRACT:

Zirconium dioxide has a very high melting temperature ( $2700^{\circ}$ ). It is, however, not possible to produce refractory material from it since it is decomposed in the course of baking. The constants of natural zirconium dioxide - of baddeleyite - are mentioned (Refs 1,2). In heating  $ZrO_2$  undergoes polymorphic transformations from a monoclinic into a tetragonal modification (at about  $1000^{\circ}$ , Refs 3,4; to be quite exact, at  $950 - 1150^{\circ}$ , Ref 5). This transformation is reversible and is accompanied by large volume changes; this is also the cause of decomposition in the case of baking. At certain conditions of thermal treatment the trigonal modification can also be produced (according to Ref 6). The conditions of existence at this form have hitherto not been completely determined. In order to produce refractory

(Uluchsheniye stoykosti svodov koksovykh pechey)

PERIODICAL: Koks i Khimiya, 1958, Nr 11, pp 26-29 (USSR)

ABSTRACT: The durability of various types of refractory bricks used in the edges (pusher and coke side) of coke oven roofs was investigated. As these bricks are submitted to continuously acting sharp temperature variations from 500-600 to 1000-1100°C the durability of silica bricks is low. The All-Union Scientific Research Institute for refractories produced and tested various types of refractory bricks, mainly chamotte based on kaolinite (Table 1). Chamotte was prepared from pure kaolinite by a plastic method and fired to 1500°C with 8 hours soaking at the final temperature. The composition of refractory bricks 85% of crushed chamotte (with a considerable proportion of coarse fractions 6-3mm 21%, 3-2mm 14.8% and 2-1mm 9.4%) and 15% of kaolinite. The bricks were made by pneumatic stamping, dried and fired at 1460°C. Properties of the bricks are given in Table 1 and their behaviour in service...

A. Z. Summary.

REPORT: Code book is intended for engineers and technicians working in ceramic technology.

OPTIONAL: The book consists of 20 articles on the development and use of new ceramics in the Soviet metallurgical industry. D. I. Gavrilov, in the first paper, presents the properties for development and research problems for the production of refractory materials. In the second article, the properties of refractory materials are discussed, with recent developments in the field. In general, the articles deal with recent developments in the fields of metal and metallo-refractories for blast and open hearth furnaces, and for the reduction of calcium and special equipment used in continuous casting and in the treatment of steel. A. S. Baranov discusses the technology of manufacturing magnetic and ferrimagnetic substances which frequently contain lime brick and clay. Several authors state that good results were obtained with clay.

CONT. 2/2

OPTIONAL: Clay brick and lime brick made of magnetite and chromite compounds. The application of new refractories, insulating materials, high temperature refractory lining bricks, and cables, combined with advanced techniques in lining furnaces, are said to have been developed in the Soviet Union. O. N. Margulis and A. G. Shchukin discuss the use of "tagged" atoms of radioactive elements between refractories and insulating materials. O. N. Margulis describes the use of "tagged" atoms of radioactive particles. It is suggested that the introduction of radioactive particles by the ordinary methods employed at the Krasnoyarsk plant and V. D. Kostyuk and V. D. Zhdanov cover the use of light-weight lime brick in industrial furnaces. The last paper written by L. A. Matveyev compares and evaluates the physical properties and service life of clay, lime, firebrick, fireclay brick, lime brick and bricks containing alumina cement, graphite, diatomite, and pumice accompanying the paper. For reference see table of contents.

MARVELS, O. M.

Changes in the phase composition of an oxidized refractory brick from primary coke after service. I. I. Karyakin  
and O. M. Margolin (Institute of Refractory Materials, Kharkov),  
Ognyanov 27, 123-6 (1957); Cl. C. A. 51: 5379. — Brick of  
100% Polozhok kaolin is produced from 85% calcined chama-  
cite and 15% kaolin binder. It is used in the steel industry,  
especially in kilns with a service temp. of 1350-1450° in  
which they are exposed to Fe oxide scale dust. While the  
unchanged cooler parts of the brick, after 1 year of service,  
showed the normal microscopic features with mullite needles,  
quartz, cristobalite, and glass. In the hotter zones near the  
scale-covered surface there is a peculiar short-prismatic  
"isometric" form of mullite crystals with  $\gamma = 1.600-1.620$ ,  
and  $\alpha = 1.648-1.676$ , systematically increasing evidently by  
increasing contents in  $\text{Fe}_2\text{O}_3$ . Towards the hot surface the  
crystals grow from 15 to 40  $\mu$  in length, embedded in an  
orange-yellow glass with  $\gamma = 1.640-1.652$ . In this glass ap-  
pears a 2nd, optically normal and fine-granular, mullite. The  
chem. analysis of isolated isometric mullites showed  
 $\text{Al}_2\text{O}_3$  28.55,  $\text{Fe}_2\text{O}_3$  2.45, and  $\text{SiO}_2$  29.07%. The (010) in-  
terference line in the x-ray diagram, which has normally a  
 $\lambda = 1.1866 \text{ \AA}$ , is increased by the  $\text{Fe}_2\text{O}_3$  content to 1.1879  
 $\text{\AA}$ . Evidently, for the formation of this isometric mullite  
a temp. above 1450°, and the presence of  $\text{Fe}_2\text{O}_3$  scale, to-  
gether with a long period of heat exposure as it is given in the  
metallurgical kilns and combustion chambers, are neces-  
sary. W. Hiltner

Sheaths for immersion thermocouples. (Cont.)

magnesite or zirconia coating can withstand 6-13 immersions. In Fig.2 a view of sheaths after 4 hours' immersion is given. It is concluded that using the above sheaths the control of metal temperature either by repeated immersions or by a continuous (4 hours) immersion is possible, but a proper design of the thermocouple itself should be developed.

There are 2 figures and 4 references, including 1 Slavic.

TITLE: Sheaths for immersion thermocouples. (Nakonechniki dlya termopar pogruzheniya).

PERIODICAL: "Stal'" (Steel), No.8, 1957, pp.714-715 (USSR).

ABSTRACT: Methods of producing refractory thermocouple sheaths for immersion thermocouples resistant to thermal shock and able to withstand not only a large number of short immersions but also prolonged immersion, were investigated. T.K.Kazanskaya (laboratory assistant) participated in the investigation. It was established that the best method of manufacturing is by freezing a layer of a mixture of refractory powder with paraffin and oleic acid on to an immersed rod (at 50-70 C). It is stated that the appropriate compositions for manufacturing various refractory sheaths were established but no details given. As all refractory sheaths produced cracked on immersion, two types of protective coatings based on metallurgical magnesite and zirconia stabilised with lime were developed. The size distribution required for the above two materials are given. As a binder, an alcoholic sulphite lye was used. Tests carried out in a high frequency furnace at 1600-1700C indicated that sheets from technical corundum coated with a

Bracuation of the distribution of small additions of radioactive calcium to plastic masses. E. V. Levintov, A. N. Lyulchenko, O. M. Maslina, and D. M. Shakhlin (Inst. Refractory Materials, Kharkov). Ogneupory 12, 20-31 (1957); cf. C.A. 51, 14226o. — The radioactive tracer method is used for the testing of pressed refractory brick by using a Ca<sup>45</sup>-contg. CaCl<sub>2</sub> soln. In the batch water and its pptn. by NH<sub>4</sub> oxalate or soda to avoid a diffusion of the indicator to the brick surface. For cylindrical samples of different brick compositions (90% kaolin + 10% Chasov-Yar clay; 60% kaolin + Chasov-Yar clay; and 40% Al<sub>2</sub>O<sub>3</sub> + 60% Chasov-Yar clay) the distribution of Ca<sup>45</sup> on the surface and in the interior was carefully detd. by common Geiger-counter methods. There is only a slight enrichment on the surface if 1% of the oxalate precipitator soln. is applied. The batches (400 kg. in the industrial expts.) were indicated with the intensities of 500 mc./ton in a CuCl<sub>2</sub> soln. with 0.04 me./ml. and a bat. of minimum of 30%. A sufficiently homogeneous distribution was realized for the Ca<sup>45</sup> in the plastic brick masses after a twice- or thrice-repeated reprocessing by tamping, and in the hydraulic press, if drying is strictly avoided. — W. Kiel

Short Reports. Conference of the Scientific-Technical Council of the Institute  
for Refractories in Khar'kov

131-12-8/9

4.) A.P. Sarmin, head of the Geological Laboratory for Raw Materials of the Leningrad Institute for Refractories, spoke about the geological and technological characteristic of the kaolin-hydrazillite raw material found in the Arkalyk deposits in the Kazakh SSR.  
5.) Professor G.V. Kukolev and his collaborator (Khar'kov Institute for Refractories), investigated the influence exercised by additions upon the sintering of kaolins. 6.) O.M. Margulis, the scientific collaborator of the Khar'kov Institute for Refractories, gave a report on the technology of the production of the testing of unburnt kaolin products in practice, the durability of which in furnaces is often greater than that of burnt ones. Finally, quite an amount of work was mentioned which ought to be carried out.

TITLE: Short Reports (Kratkiye soobshcheniya). Conference of the Scientific-  
Technical Council of the Institute for Refractories in Khar'kov  
(Sessiya nauchno-tehnicheskogo soveta instituta ogneuporov v Khar'kove)

PERIODICAL: Ogneupory, 1957, Nr 12, pp. 567-568 (USSR)

ABSTRACT: This conference took place on October 28/30, 1957, and was attended by many representatives of scientific institutes and the corresponding industries. Reports were heard on various problems connected with refractories, of which the following met with the greatest interest:  
1.) Professor Karyakin, L.I., head of the petrographical laboratory of the Khar'kov Institute for Refractories, spoke about the results obtained by research work connected with kaolins and clays of the Ukraine. 2.) I.G. Orlova, Candidate of Technical Sciences, gave a report on the research work carried out concerning sintering and swelling up of refractory clays and kaolins when heated. 3.) T.S. Ignatova, scientific collaborator of long standing of the Ural department of the Leningrad Institute for Refractories, delivered a report on the results obtained by laboratory work as well as by the industrial testing of the rational utilization of primary kaolin found in the Kyshtym deposits and of the semiacid clays discovered in the Ural deposits.

The Wear of Refractories in Various Zones of the Blast Furnace

131-12-5/9

shows the working results obtained by refractory bricks in the various zones. The aforementioned investigations confirmed the necessity of using refractories of high specific weight and volume stability at high temperatures. As a way for a further increase of the strength of the lining the use of carbon materials is mentioned. There are 1 figure, 5 tables, and 17 references, 8 of which are Slavic.
