Critical heat flows for...

have no essential influence on q_{cr} if the internal diameter is more than 4 mm, the width of annular gaps more than 1 - 2 mm, and that of plane gaps more than 1.3 mm. If $x \geq 0$, q_{cr} is a hyperbolic function of the relative length l/d_{equ} . Since this is not a characteristic parameter, the quantity $\sigma/(\gamma' - \gamma)$ is chosen as characteristic length l_0 . (The singly primed quantities refer to the liquid, the doubly primed ones to the vapor). The effect of λ' on q_{cr} is negligible. If the parameter $w_0 l_0 / \sigma^2$ exists, $w_0 l_0 / \sigma^2$ can be omitted. The rate of mass flow, w_g ($\text{kg}/\text{m}^2 \cdot \text{h}$) is chosen as the characteristic of flow rate and phase composition of the boiling medium so that, instead of (1) $\frac{q_{cr} \mu'}{\sigma r} = f(\frac{\sigma}{\rho g}, \frac{r}{c' T_s}, \frac{\gamma' - \gamma}{\gamma'' - \gamma})$ (2)

can be taken as new "criterial system". The first parameter may be defined by

$$\frac{W_{0l}}{\sigma \gamma'} = F_r^* \quad F_r^* = \frac{w_g^2}{g} \sqrt{\frac{\gamma' - \gamma}{\sigma}} \quad (A),$$

$$w_0 l_0 = \frac{g}{\sqrt{2}} \frac{\sigma}{\gamma' - \gamma} \frac{\gamma' - \gamma}{1 - \gamma}$$

Critical heat flows for...

$r/c_p T_s$ may be regarded as a measure of thermodynamical similarity, $\dot{m}/r = x$ is the relative enthalpy of the flow. The actual relations holdin; within system (2), as determined experimentally and given in the table. These relations are evaluated and discussed for the following special cases: (1) A non-pulsating system with $x > 0$, (2) a pulsating system with $x \gg 0$, and (3) a non-pulsating system with $x < 0$. The result of the last case, for instance, is given by

$$\frac{q_{\text{cr}} W'}{\sigma Y^*} = 0.174 \left(\frac{c_p T_s}{r} \right)^{0.8} K_W^{0.1} \cdot \left[1 - 0.45x \left(\frac{Y'}{Y^*} \right)^{0.8} \right] \quad (7).$$

It is valid if $q_{\text{cr}} > q_s$, and the thermal flow is given by

$$q_s = 0.023 \frac{\lambda}{d} Pr^{0.3} \frac{W' d}{\mu g} (t_e - t_n). \quad (7).$$

The relations are illustrated by graphs. There are 4 figures, 1 table, and 14 references; 10 Soviet and 4 non-Soviet. The three references to English-language publications read as follows: H. Jacket, J. Mourty, Card 3/6

AUTHORS: Styrikovich, M. A., Corresponding Member AS USSR
Miropolskiy, Z. L., and Shen Chao-Yuan

TITLE: Effect of nonuniform heating along a laterally insulated vertical wall on critical thermal convection

PERIODICAL: Akademiya nauk SSSR. Doklady, v. 14, no. 4

TEXT: In connection with the design of high-power heat exchangers the authors studied the effect of a nonuniform heat source on the occurrence of a boiling crisis. Experiments were made with steam-water mixture and/or with water moving upward in a tube at heating, i.e., saturation temperature; pressures ranged from 100 - 180 atm. The flow rates were 400, 850, and 2,000 kg/m².sec. The experimental setup has been described in an earlier paper by Miropol'skiy et al. (Teploenergetika, no. 1, 1970). The arrangement consists in an open circuit with a preheater. Pressure and flow rate can be adjusted by valves. Two types of nonuniform heating of the tubes were employed. Data are given obtained with tubes with a ratio of the maximum thermal flow to the mean flow of c. 1. The maximum heat flux

Card 1, '4

Effect of nonuniform heating

thermal flow ratio was 4.9. Occurrence of the crisis crisis was determined visually. The local value of specific thermal energy at the point of the arising crisis is regarded as the critical thermal convection. The q_{crit}^{nonu} values are listed in Fig. 1 in contrast to the corresponding critical thermal convection in the case of uniform heating. The values of q_{crit}^{nonu} were found to surmount the critical values in the case of uniform heating of the tubes (q_{crit}^u) by about twice their amount. A rather complex dependence was obtained only when pulsations (100 at. 400 cm/s, π^2 -sec) developed. In this case, when incompressible water in the space of the expansion tube test tube is replaced by elastic water-vapor mixture, the q_{crit}^{nonu} values of q_{crit}^u jump like. The ratio between q_{crit}^{nonu} and q_{crit}^u is then nearly equal to that given above. Experiments with increasing thermal flow in the direction of the moving medium showed that q_{crit}^{nonu} was only half of q_{crit}^u , when the crit-

sis was located near the exit of the tube. On the other hand, q_{crit}^{nonu} lay considerably above the q_{crit}^u value when the crisis was near the entrance of the tube. The authors show in the discussion of the results that the latter are determined by the percentage of vapor in the boundary layer. There are 2 figures and 3 Soviet-bloc references.

TITLE: Critical heat flows in the boiling of water in channels

SOURCE: Teplo-i massoperenos. t. 2: Teplo-i massoperenos pri fazovykh i khimicheskikh provernoshcheniyakh. Ed. by A.V. Lykov and B.M. Smol'skiy. Minsk, Izd-vo AN BSSR, 1962, 87 - 93

TEXT: Experimental data obtained by various authors on critical heat flows are treated with the aid of dimensionless criteria, and recommendations are given for the calculation of these heat flows involving that of a steam-and-water mixture and of water underheated below saturation temperature in tubes, ring- and flat-slit channels. The following critical system for the onset of critical boiling with forced liquid flow in channels has been previously derived (ref. 1: ZhTF, v. 23, vyp. 2, 1953):

$$\frac{q_{crit}}{a' r_i} = f \left(\frac{w_0 l}{v}, \frac{w_0}{a}, \frac{r}{c_p T_0}, \frac{w_0}{w_0}, \frac{\gamma}{\gamma} \right). \quad (1)$$

Card 1/4

S/862/62/002/000/007/029
A059/A126

Critical heat flows in the boiling of

where q_{cr} is the respective critical heat flow, l_0 the characteristic linear dimension, a' the temperature coefficient of the thermal conductivity of the liquid, r the heat of evaporation, γ' and γ'' the specific gravities of the liquid and the steam, respectively, on the saturation line, w_0 and w_0'' the reduced velocities of the liquid and the steam, respectively, on the saturation line, ν' the kinematic viscosity of the liquid, c_p' the thermal capacity of the liquid, and T_s the absolute saturation temperature. When channels with $d > 4$, the width of the flat slit $\delta_{slit} < 1.3$, and $1/d_{eq} < 100$ are excluded, the geometric dimensions of the channel need not be considered in equation (1). For the forced flow of the boiling liquid in the channels,

$$l_0 = f(w_0, w_0'', \gamma', \gamma'', \sigma),$$

where σ is the surface tension, and the criterion $w_0 l_0 / a'$ in the system (1) can be excluded in the presence of the criterion $w_0 l_0 / \nu'$. When the rate of mass flow, w_g , and the relative enthalpy, Δh , are introduced, we obtain

$$\frac{q_{cr} p'}{\sigma' r} = f \left(\frac{w_g p'}{\sigma r}, \frac{r}{c_p T_s}, \frac{\gamma'}{\gamma''}, \frac{\Delta h}{r} \right) \quad (2)$$

Card 2/4

S/862/62/002/000/007/029
A059/A126

Critical heat flows in the boiling of

where μ' is the dynamic viscosity. Two cases are to be considered: a) that with the free development of fluctuations and a compressible medium between the heated section and the throttling member or the circulation impeller, and b) that with a limited development of fluctuations, in the presence of an incompressible medium at this place. Under non-fluctuating conditions and with $x (-\Delta t/r) > 0$ in tubes and annular channels,

$$\frac{q_{cr} \mu'}{dY' r} = 0.174 \left(\frac{c_p T_a}{r} \right)^{0.8} K_w^{0.4} (1 - x)^n, \quad (3)$$

where $K_w = \frac{w_p \mu'}{dY'} \left(\frac{v'}{v_w} \right)^{0.2}$, and, in flat-slit channels,

$$\frac{q_{cr} \mu'}{\sigma Y' r} = 0.224 \left(\frac{c_p T_a}{r} \right)^{0.8} K_w^{0.4} (1 - x)^n. \quad (4)$$

Under fluctuating conditions and $x > 0$,

$$\frac{q_{cr} \mu'}{\sigma Y' r} = 0.7 \left(\frac{c_p T_a}{r} \right)^{0.8} K_w (1 - x)(1 + 4x); \quad (5)$$

and under non-fluctuating conditions and $x \leq 0$,

Card 3/4

3/862/62/002/000/007/029
A059/A126

Critical heat flow in the boiling of ...

$$\frac{q_{cr}}{sy'} = 0.174 \left(\frac{c_p T_s}{r} \right)^{0.4} k_w^0 \left[1 - 0.45x \left(\frac{T'}{T_s} \right)^{0.05} \right]. \quad (6)$$

A satisfactory agreement was found between calculated and experimental data. At high velocities of flow and high negative values of x , the equation

$$q_c = 0.023 \frac{\lambda}{d} \rho v \left(\frac{w_d}{\mu g} \right)^{0.8} (t_s - t_f) \quad (7)$$

holds, where λ is the coefficient of heat conduction, g acceleration due to gravity, t_s the saturation temperature, and t_f the temperature of flow when $q_{cr} > q_s$. I.L. Mostinskiy and L.Ye. Faktorovich are mentioned. There are 4 figures and 1 table.

TITLE: Critical boiling in tubes

SOURCE: Teploperedacha. Energ. inst. AN SSSR. Ed. by
M.A.Mikheyev. Moscow, Izd-vo AN SSSR, 1962. 124-132

TEXT: A good many critical boiling tests have been made in recent years, usually whilst water is being pumped through an electrically heated stainless steel pipe. It is usually considered that the critical heat transfer rate is uniquely determined by the pressure, rate of flow and the enthalpy of the medium at the place of critical boiling. This article considers the effects of other factors, such as the distribution of heat flow over the perimeter and length of the pipe, the dimensions of the test length and of neighbouring parts of the system and the compressibility of the fluid in neighbouring parts of the system. This latter point is important because flow pulsations can develop during the tests and when neighbouring spaces are filled with compressible substances, whereas if neighbouring spaces are

Card 1/3

S/855/62/000/000/005/005
E194/E435

Critical boiling in tubes

filled with incompressible substances pulsations do not develop. Pulsating conditions are the least favourable and they must often be suppressed. It sometimes does not suffice to fit a resistance between the expansion vessel and the heated pipe. If the internal diameter of the test pipe is reduced from 8 to 3 mm there is some increase in the critical heat transfer rate. The length of the test piece can have various effects depending upon the flow conditions, particularly when pulsation is present. The thickness of the duct walls (0.4 and 2 mm respectively) and the roughness of the inner surface (even 0.12 to 0.15 mm deep transverse grooves) had little influence on the critical heat flow. The effects of increasing the pressure, the rate of flow and the enthalpy of the fluid in increasing the critical heat transfer rate are discussed. Experimental work on determination of critical heat transfer rates during the flow of water and steam/water mixtures in pipes is briefly reviewed. Although several methods of generalizing experimental results have been proposed in the USSR the empirical formulae are complicated and often contain numerous empirical constants. Reliable generalizations will only

AUTHOR: Miropol'skiy, Z.L., Candidate of Technical Sciences
TITLE: Heat transfer in steam-raising tubes during filmwise
boiling of steam-water mixture

PERIODICAL: Teploenergetika, no. 5, 1963, 49-52

TEXT: With forced circulation the transition from bubble to film-wise boiling is not always associated with a great rise in tube-wall temperature. Available experimental data on this point relates to a fairly narrow range of pressure and flow rate, and little has been published about the influence of tube geometry. Accordingly a study was made of heat transfer during film-wise boiling in a vertical tube of 8 mm inner diameter electrically heated over a length of 1500 mm, with wall temperature measurement at 11 distances from the start of the heated section. Super-critical steam delivered from a single-pass boiler was cooled and throttled before passing through the experimental rig. Thereafter the steam was cooled in a heat exchanger and passed to a measuring tank. The temperature distribution was determined at the 11 check sections with constant flow conditions. Then the heat

Card 1/4

E194/E455

Heat transfer in steam-raising ...

input to the tube was gradually raised to a new value until further increase was prevented by the tube wall temperature reaching 600°C. At pressures below 180 atm in the initial sections of the heated tube, the impairment of temperature conditions occurred at higher steam contents than in sections further away from the start of the heating. When $\ell/d > 100$, conditions ahead of the tube had no appreciable influence. The experimental curves which are given show that in the region of steam content where normal bubble boiling occurs, the wall temperature is only a few degrees above the saturation temperature whatever the speed or the steam content of flow. Beyond the critical point the wall temperature reaches maximum values with steam contents close to the critical value, but the temperature gradually falls and when the steam content reaches unity the wall temperature may be calculated by

$$Nu_{\text{II}} = 0.023 Re^{0.8} Pr^{0.8} \quad (2)$$

where, II denotes steam and ct denotes wall. This form of expression signifies that during critical boiling the normal

Card 2/4

S/096/63/000/005/004/011
E194/E455

Heat transfer in steam-raising ...

transfer of heat from the nucleus of the flow to the boundary layer is disturbed and heat transfer is governed mainly by the properties of the steam in the layer near the wall and its speed. For a given mass rate of flow, as the heat flux increases the heat-transfer conditions are worse at low steam contents and then wall temperatures are very high. The heat-transfer coefficient to a steam-water mixture with steam content above the critical value is approximately proportional to the change in linear speed of steam-water mixture to the power of 0.8. On the basis of the results the following formula is recommended for calculating heat-transfer coefficients during the flow of steam-water mixture in pipes beyond the critical boiling condition

$$Nu_x = 0.023 \Pr_{ct}^{0.8} Re^{0.8} \left[x + \frac{Y''}{Y'} (1-x) \right]^{0.8} y \quad (7)$$

where $Nu_x = \frac{axd}{\lambda^N}$ and $Re'' = \frac{Wgd}{\mu''g}$. When available experimental results are plotted in suitable dimensionless coordinates, most of them lie within $\pm 25\%$ of the curve represented by the above

"Further Utilization of Plate Self-Modulation," by A. I.
Miroshin, chief engineer of a project, Planning Institute of
the Ministry of Communications USSR, Vestnik Svyazi, No 11,
Nov 56, pp 8-11

At present there are in the USSR several medium-wave and short-wave transmitting stations operating on the principle of plate self-modulation, which proved to be 20-35% more efficient in power consumption. The transmitting power of these stations was almost doubled with the change-over from grid modulation to plate self-modulation.

In 1954 the Planning Institute of the Ministry of Communications USSR developed general circuits for plate self-modulation, suitable for 10- and 100-kw stations. These new circuits for the plate self-modulation of radio transmitters were tested under actual operating conditions and proved to be quite satisfactory from all angles.

On one of the powerful transmitting stations, where plate self-modulation was tested, the coefficient of nonlinear distortion was less than 5% at 95% modulation in the frequency range of 100 to 5,000 c.

At present three powerful long-wave radio stations are being reconstructed for operation on the plate self-modulation principle.

ABSTRACT:

A number of short-, medium- and especially of long-wave transmitters have been adapted to auto-plate-modulation owing to an initiative by the GSPI and the Radio Administration at the Ministry for Postal and Telecommunication Service of the USSR as well as by the specialists. The introduction of this change and the elaboration of a scheme for it was achieved by the reconstruction of existing transmission stations with grid modulation. This was achieved at great expenses. At present 4 schemes of auto-plate-modulation are introduced: 1) for medium- and long-wave transmitters of medium and great power 2) ditto, of smaller power. 3) ditto, with strong cascade according to the two-block scheme. 4) for short-wave transmitters with strong cascade according to a scheme with earthened grid. The description of the scheme follows. Experience shows:

Card 1/2

Introduction of Auto-Plate-Modulation

108-13-3-3/13

that the transmitters with auto-plate-modulation are not less stable in operation than the old stations. Practice shows that in using auto-plate-modulation there are real possibilities for abandoning compensating valves. The given schemes - Figures 5 and 6 - can be recommended as schemes without compensation valves. By their means high acoustic parameters are obtained at increased efficiency this way". G. Kruglov's invention is at present being realized. There are 6 figures, 4 tables, and 2 references 2 of which are Soviet.

S. F. Karabilova.

PURPOSE: The booklet is intended for participants personnel engaged
in introducing the new initiative mentioned.

COVERAGE: The author explains the problem of tuning radio trans-
mitters by a method developed by N. D. Kruglov, called "automatic
plate modulation". On the initiative and with the assistance of
the Main Administration of the Ministry of Communications, USSR,
and GSPI, several short-, medium- and long-wave radio-broadcasting

Card 1/3

Tuning of Radio Transmitters (Cont.)

SOV/3566

stations have been converted to this system of modulation. The change-over, accomplished with comparatively low outlays, has resulted, according to the author, in an increase of power (by 70 to 100 per cent), efficiency (from a previous 18-20 per cent to 37-40 per cent) and in an improvement of performance of transmitters. The author describes the results of his own experience in converting several powerful broadcasting transmitters and presents calculations of some circuit components and stage operating conditions. He also presents recommendations on the regulation of power and frequency. There are 11 references, all Soviet (in Russian). The book is 112 pages.

TITLE: Passive radio relay stations

PERIODICAL: Vestnik svyazi no. 1, 1966

TEXT: A passive relay station is described. The formulas of the theory are derived and a numerical example - given. A figure of a typical relay station widely used in Japan. Other figures show an experimental passive relay-station in the form of a relay line point developed by Chinese specialists. Fig. 4 shows a diagram of a relay line using a passive relay-station in the form of a point. This relay line has the following characteristics. The power arriving at the relay station from station no. 1, is $P_1 = P_1 \cdot A_1 \cdot A_r / d^2$, watt, where P_1 denotes the power emitted by station no. 1, A_1 - the effective aperture of the antenna of station no. 1 in square meters, A_r - the effective area of the relay station, d - the wavelength in meters. An analogous formula holds for the power P_2 arriving at

Card 1/2

Passive radio-relay-stations

S 1162 : 1
D299 D'1

station no. 1 from the relay station. Formulas are given for the attenuation. These show that the attenuation, and therefore the relay-station is weaker, the larger the angle of incidence. The smaller the term $d_1 d_2 / d_1 + d_2$. The design of the relay-station amounts in fact to calculation of its area proceeding from the permissible attenuation. The latter depends on the length of the relay line, the type of radio-relay equipment used and the international noise-level standards for telephone channels. Formulas are derived for the permissible attenuation and for the minimum power required at the receiver input. The noise level at the relay line Tokyo-Osaka (with 240 telephone channels) is 4 μ . After the area of the relay-station has been calculated, its inclination is being determined. In practice, one takes an angle of aperture of the relay surface equal to 1 $^{\circ}$. For reducing the wind pressure, the relay plate can be perforated. With a 4 \times 1 \times 1 mm angle of arrival of 38 $^{\circ}$, hole-diameter 5mm and distance between holes 10 mm, the ratio of the energy received at the relay-station is 1.1. The relay-stations can have one or two metallic plates; the choice depends on the desired angle of incidence. A formula is given for the

TITLE: Two-parameter Flaw Detection in Rails (Dvukhparametrovaya detek-
toskopiya rebsov)

PERIODICAL: Izv. vyssh. uchebn. zavedeniy. Fizika, 1958, Nr 1, pp 70-74

ABSTRACT: The author proposes to measure the phase of the voltage generated
in an electromagnetic pickup probe together with its amplitude. It is
established that depending upon the character of the flaw the change of
phase is more pronounced during the passage through a crack or a sim-
ilar deep flaw the phase changes by 180°, whereas a surface flaw dis-
places it appreciably less. The author assumes that two simultaneous
measurements would make it possible to determine the degree of danger
presented by a flaw. The work was performed with two types of SFTI
apparatus.

Physical Fundamentals of the Method of Magnetic
Detection of Defects by Means of Simultaneous
Magnetization of the Specimen with Direct and
Alternating Fields

PERIODICAL: Izvestiya vysashikh uchebnykh zavedeniy, Fizika.
1960, No.4, pp.139-146

TEXT: During development work on apparatus for defect detection in rails by induction methods, it was found that, in addition to defects, a.c. defectoscopes revealed very clearly sections of the rail which were magnetized by a d.c. field. This observation led to investigations on the problem of detection of local magnetic nonuniformities directly relevant to the problem of detecting hidden (internal) defects by means of a.c. fields. The possibility of detection of changes in the magnitude and distribution of the eddy currents in the defect zone. In this paper the changes are investigated in the density of a.c. eddy fields in the region of magnetic

Physical Fundamentals of the Method of Magnetic Detection of Defects by Means of Simultaneous Magnetization of the Specimen with Direct and Alternating Fields

nonuniformities caused, by means of the polarization field of an internal crack, during magnetization of the specimen by a d.c. field. The solution is reduced to the following two problems:
1) determination of the permeability of the material as a function of the field H in the specimen with an internal defect in the case of magnetization by a uniform d.c. field H_0 ;
2) calculation of the changes in the density j of eddy currents induced by the alternating field of an external lumped source (pole), in a conducting specimen which has an internal defect with the polarization field H_0 . Both these problems are basically nonlinear ones. In view of the difficulty of accurate solution of nonlinear problems, a simplification is introduced, namely, each of the considered problems is partly linearized, i.e. where possible it is assumed, in calculating the field of the defect that the permeability of the material does not depend on H_0 and, in calculating the density of the eddy currents, it does not depend on the alternating component of the field in the

Defects by Means of Simultaneous Magnetization of the Specimen with
Direct and Alternating Fields

specimen. The solution arrived at on the basis of these assumptions yields useful calculating data which, together with experimental results, will yield generally valid relations for those values which determine the possibility of detecting a concealed magnetically polarized defect by means of the alternating magnetic field method. The calculation of the defect field and determination of $\mu(H)$ is described as well as the calculation of the density of the eddy currents in a magnetized semiconducting medium. On the basis of these calculations, optimum values of H_0 and of the frequency of the alternating field are determined for which internal defects can be detected most easily. The theoretically derived relations were checked on rail steel specimens having artificial defects in the form of an eccentrically drilled 15 mm diameter hole into which two tightly fitting rods were driven in from both sides and the contact area represented the artificial internal defect. The experimental specimens were clamped to form a closed magnetic circuit and d.c. magnetization with currents

Card 3/4

S/139/60/000/004/015/033
E073/E535

Physical Fundamentals of the Method of Magnetic Detection of Defects by Means of Simultaneous Magnetization of the Specimen with Direct and Alternating Fields

between 0 and 10 A was applied. As an a.c. source, the end of a straight-line solenoid was chosen. By means of this test-rig, the detection characteristics of the polarized internal defect were investigated for a.c. frequencies of 500, 1000 and 2000 c.p.s. The best conditions for detection of a concealed defect were obtained for a d.c. field of an intensity corresponding to the upper bend of the magnetization curve (Fig.5). Analysis of the effect of the frequency (Fig.6) shows that the possibility of detection in the case of an induction method follows a square law (curve 1), whilst in the case of detection on the basis of changes in the eddy currents the possibility of detection increases almost linearly with increasing frequency (curve 2, Fig.6). The experimental results are in satisfactory agreement with the theoretical conclusions. There are 6 figures and 7 references: all Soviet.

TITLE: Evolution equations of a rarified gas

SOURCE: Leningrad. Universitet. Vestnik. Seriya matematiki, mehaniki i
astronomii, no. 1, 1964, 99-107TOPIC TAGS: gas theory, rarified gas, Vallander equation, Markov process,
rarified gas evolution

ABSTRACT: This paper attempts to derive a relationship between the theory of a rarified gas, developed on the basis of the integral equation of S. V. Vallander, and the theory of a purely discontinuous, random, Markov process, as studied by V. Feller and V. M. Dubrovskiy. The probability that an atom will be displaced from an initial point $\{r_0, u_0\}$ in phase space to a region E at the instant t , is expressed by $P(E, t | r_0, u_0, t)$. This probability satisfies the equation:

$$P(E, t | r_0, u_0, t_0) = P(E, t | r', u', t') P(dE', t' | r_0, u_0, t_0).$$

The paper is then devoted to deriving equations for this probability and to

TITLE: An installation for aseptic preservation of liquid and puree-type foodstuffs
in large storage tanks. Class 53, No. 174520

SOURCE: Byulleten' izobreteniy i tovarnykh znakov, no. 17, 1965, 116

TOPIC TAGS: food technology, food product machinery, food sanitation

ABSTRACT: This Author's Certificate introduces: 1. An installation for aseptic preservation of liquid and puree-consistency food products in large storage tanks. The unit consists of interconnected sterilizer pipelines made according to Author's Certificate No. 168108, a vacuum cooler, hermetically sealed tanks equipped with locking devices made according to Author's Certificate No. 168109, and bacteriological filters. The unit is designed for continuous operation and for preventing admission of any unsterilized product. The unit is equipped with a discharge reservoir and with an intermediate collector connected to the reservoir and to the sterilizer. 2. A modifiable pipe between the hermetically sealed tanks and the vacuum cooler, and a portable pump with a flexible hose for unloading the food products from the tanks.

TITLE: Gregory Antonovich Tsulukidze (Григорий Антонович Чулукидзе)
PERIODICAL: Tr. Gruz. politekhn. inst., 1986, Nr 4 (42), pp 3-20
ABSTRACT: G. A. Tsulukidze, an active member of the Ac. Gruzinskaya SSSR, was an outstanding Soviet scientist in the field of mining. Scientific biography of G. A. Tsulukidze includes the course of study in mining technology and in mechanization of the coal-extracting industry, and works on the methods of underground exploitation of mining resources in Georgia, all of these were originally published in the Georgian language (they dealt with coal, manganese, roofing shale, petroleum and others). His latter work pertained to

Card 1/2

Gregory Antonovich Tsulukidze (cont.)

explorations for mining resources, to the planning of such explorations in the Gruzinskaya SSR and to the future of mining in the republic; his writings also dealt with the subject of mechanization of mining, with mining structures, mine ventilation, safety, enrichment of ores and the utilization of manganese, coal, etc. After studying the existing classifications by native and foreign authors, he worked out, in a number of his writings, an original classification for the subsurface methods of ore extraction. Tsulukidze clarified the complicated problem of dealing with soil resources in mining works and particularly in the Chiatura manganese mine which he used as an example. His works on the extraction of petroleum by means of shafts and his analysis of the Tavibul'skoye hard coal mine are also well known. The main work of G. A. Tsulukidze, "Metody podzemnoy razrabotki mestorozhdeniy poleznykh iskopayemykh" (Methods of Underground Extraction of Ore) was published between 1941 and 1952 as a textbook in the Georgian, Russian and Hungarian languages. The bibliography of 67 titles is included.

Hardness of Carbon Solid

Solution of Iron-Carbon

System at High Temperatures

K.A. Osipov, E.H. Miroshkina

Experiments (described in some detail) were carried out with austenite in the interval 910-1,100 deg.C. Hardness was determined with the aid of a four-faced diamond pyramid in vacuo. Pressure on the diamond pyramid was 1 kg, and the time varied between 15 and 600 sec. Brief tests showed that hardness of austenite was proportional to the carbon content. Longer tests at high temperatures showed that deformation of austenite grew proportionally to the carbon content. Solid solutions with stronger inter-atomic bonds and minimum distortions of the lattice should, therefore, have greater resistance to plastic deformation. (Bibl.5)

AUTHOR: Osipov, K. A., (Moscow); Miroshkina, Ye. M., (Moscow); Sotnichenko, A. L,
(Moscow)TITLE: Investigation of the creep of ϵ - and β -modifications of Ti-Zr alloysSOURCE: AM SSSR. Izv. otd. tekhn. nauk. Metallurgiya i gornoye delo, no. 2, 1963,
146-152TOPIC-TAGS: titanium-sirconium alloys, ϵ -alloys, β -alloys, creep, activation energy, creep mechanism

ABSTRACT: The creep behavior of ϵ - and β -modifications of polycrystalline Ti-Zr alloys in a vacuum of about 1×10^{-4} mm Hg under a constant tensile stress has been studied in an effort to determine the mechanism of steady-state creep. The alloys (25.15, 50.01, and 75.50 at% Zr, 0.006% max N, 0.03% max C and O₂, and 0.03% max Fe) were vacuum-arc melted, forged into rods, annealed for 24 hr at 800C and for 168 hr at 450C (alloy with 50 at% Zr) or at 550C (alloys with 25 and 75 at. % Zr). The ϵ -modification alloys were tested at temperatures from

Card 1/2

L 11291-63

ACCESSION NR: AP3000917

20 to 200°C under a stress of 30 to 70 kg/mm². The activation energy ΔH of the steady-state creep, determined from $\ln \dot{\epsilon} - 1/T$ curves ($\dot{\epsilon}$, rate of the steady-state creep; T, absolute temperature), was found to be constant at stresses higher than 40-50 kg/mm² (depending on alloy compositions) and equal to 8100, 6900, and 8000 cal/mol for Zr contents of 25, 50, and 75 at%, respectively. These values are very close to the limiting values of activation energy calculated under the assumption that in α -Ti-Zr alloys the creep-induced activated state of atoms or ions corresponds to that of a local allotropic transformation. This leads to the conclusion that the creep of α -Ti-Zr alloys under high stresses is affected by a mechanism directly associated with a local allotropic transformation. Creep tests of the β -modification of Ti-Zr alloys were carried out under a constant tensile strength of 0.5 kg/mm². Analysis of the data obtained shows that the steady-state creep of the β -modification of Ti-Zr alloys occurs through a mechanism directly associated with melting. Orig. art. has: 2 formulas, 6 figures, and 4 tables.
