available at the power station, is sketched in Fig.1., and the procedure used to manufacture the sorbent is described. The chemical analysis of the sorbent was: 35.5% MgO; 22% MgCl<sub>2</sub>; 1.2% CaCl<sub>2</sub>; 0.8% FeCl<sub>3</sub>, the remainder being mainly water. Each filter was loaded with 0.8 tons of sorbent, to the heights given in Fig.2. Before the filters were used, excess chloride was washed out of the sorbent; a graph of the washing process appears in Fig.3. Full-scale operation of the filters commenced in March, 1967 and the results of six months operation are plotted in Fig.4. which shows that the silica content of the treated water has gradually risen to about 1.4 mg/litre SiO<sub>2</sub>. The increase has probably resulted from contamination of the sorbent with organic substances and iron oxides. The chemical analysis of the sorbent after 2½ months operation is given in Table.2; although the chemical composition has altered, the mechanical strength is unchanged. There is a considerable increase in the silica and iron-oxide contents of the sorbent. The silica content of the water was somewhat higher than it should be, and attempts to improve matters by raising the treating temperature by 5°C to 42°C were ineffective. Tests were made of the influence of rate of

Card 2/4

de-silication of feed-water for high-pressure boilers.

filtration on the effectiveness of purification. It will be seen from the graph in Fig.5. that as the rate is increased from 4 to 10.7 m/hr the silica content increases by 0.51 mg/litre. The results plotted in Fig.6. show that by reducing the hydrated alkalinity of the water delivered to the sorbent filters, their effectiveness is improved. However, tests could not be made at pH values below 8.5 because coagulation of the water by the iron sulphate was impaired. Thus the best condition for removing silica from water by magnesite sorbent is the carbonate condition of liming with which the pH value of the water is 8.5 - 9. In six months of operation the magnesite sorbent absorbed 572 kg of silica, a third of the theoretical capacity. The use of magnesite sorbent simplified the process of water treatment and reduced the silica content of the feed water from its former value of 0.8 - 1.3 mg/litre to 0.25 - 0.5 mg/litre. Boiler blow-down was correspondingly reduced. There is an editorial

ABSTRACT: An attempt is made to elucidate the role of certain kinetic factors in systems where no occlusion of impurities by the precipitate should occur in the state of equilibrium. The case of nonequilibrium systems which slowly tend toward an equilibrium is considered, and the rate of this transition for two coexisting precipitates is discussed. Specifically, the time of dissolution of nonequilibrium precipitates formed by a drop of precipitant (10.2 N ammonia solution) in 1.5 and 3% rare earth nitrate solutions was studied. This

SOURCE: AN SSSR. Sibirskaya otdeleniya. Izvestiya. Seriya khimicheskikh nauk, no. 3, 1965, 150-152

TOPIC TAGS: boron, boron mineral, chemical separation, boron compound

ABSTRACT: A study has been made of the effects of the nature and concentration of the acid on the boron extraction from acid solutions of datolite mineral using methanol as extracting agent. Procedures of the acid digestion of datolite containing 18.2% B<sub>2</sub>O<sub>3</sub>, distillation of the methyl borate, and analysis of the condensate were described. Tabulated data indicated that the maximum percent of boron extraction (about 95%) was achieved from 52% H<sub>2</sub>SO<sub>4</sub> and 7% HCl solutions. These acid concentrations were considered optimum for B extraction. By saponification of methyl borate with alkali or soda ash, 98--99% of the

**ABSTRACT:** The investigation was carried out in two open-hearth furnaces of different plants. The technical requirements can be summarized as follows: With respect to feed water: Practically full transparency (not less than 150 cm crosswise), a hardness of not more than 0,1 mg/liter, an oxygen content not exceeding 0,1 mg/liter, an overall saline content of up to 10 ‰, and the absence of free carbon dioxide, if the water is heated above 25 - 30° C.

With respect to evaporating water: The water should comply with the operating regulations determined by pyrometric tests: (An alkaline content of not more than 20 - 25 and not less than 10 meval/liter, a saline content of 15 - 20 mg/liter presumably, not 15000 - 20000 as in the abstract in the paper).

With respect to the steam: Saline content corresponding to the specifications for feedwater in boiler systems. The content of carbon dioxide is not specified. The separators have to be equipped with

**PERIODICAL:** Izvestiya Akademii Nauk SSSR, Otdeleniye Tekhnicheskikh Nauk, 1958, Nr 11, pp 89-91 (USSR)

**ABSTRACT:** During the process of burning of a welding arc a considerable part of the energy which is released in the near electrode regions is spent on fusion and evaporation of the electrode material. It was found in earlier work of the authors (Ref 1) that due to the considerable concentration of the arc energy in the anode and cathode spots, intensive illumination fluxes are emitted from the finer particles of the electrode material. These fluxes transmit a considerable part of the energy from one electrode to the other, which influences appreciably the energy distribution between the electrode and the component. The energy distribution between the electrode and the component is affected to a great extent by the transfer from the electrode to the component of large

Card1/4

SOV/24-58-11-20/42

Thermal Balance of a D.C. Welding Arc in Gases During the Period of Drop Formation

drops of liquid metal. Thereby, the energy transfer by the light flux is continuous, whilst the energy transfer caused by the large drops is periodic and has a certain frequency. However, the drops of the liquid metal do not have a very high energy content and will not affect greatly the process of fusion of the parent metal. Therefore, for evaluating the process of penetration as well as the process of fusion of the electrode metal, it is of interest to investigate the thermal balance of the arc during the period of drop formation. The experiments related to a d.c. arc with a burning time of 0.03 to 0.7 sec, which is shorter than the time of separation of the drop from the electrode. The experiments have shown that the instantaneous thermal balance of the arc during this time remains practically constant. The investigations were carried out on a test-rig which enabled the following to be done simultaneously: measurement of the energy in the electrode and the component and of the radiation energy of the arc and also to photograph the arc. The heat in the electrode and in the component were measured separately

Card 2/4

SOV/24-58-11-20/42

Thermal Balance of a D.C. Welding Arc in Gases During the Period of Drop Formation

in two water calorimeters with variable temperature and an isothermal shell of a capacity of 150 millilitres each. As a component a 37 mm dia., 12 mm high cylinder was used, whilst the electrode was a rod, 10 to 12 mm long, fixed in a steel cylinder of 37 mm dia. and 7 mm high. 0.5 to 1 sec after quenching the arc, the component as well as the electrode were placed into the calorimeters. The full radiation energy was measured in the direction perpendicular to the arc axis by means of a probe consisting of a copper disc with a welded-on thermocouple. The main experiments were effected for a Fe-Fe arc of direct and reverse polarity, 60 to 1300 A and an arc length of 2.2 to 20 mm; the electrodes were of 5 mm dia. A series of experiments were also carried out for determining the thermal balance of a W-Ti arc inside an argon atmosphere. The current intensity influences greatly the thermal balance of the arc. In a Fe-Fe arc of direct polarity burning in air 40 to 45% of the full power of the arc is released in the electrode and 30 to 37% in the component in the case of low current intensities up to about 150 A; for current

Card 3/4

SOV/24-58-11-20/42

**Thermal Balance of a D.C. Welding Arc in Gases During the Period of Drop Formation**

intensities of 300 to 3000 A the proportion of energy released in the electrode is reduced by 30-35% and that in the component is increased by 45-50%, Fig.1a. The observed redistribution of the arc energy between the electrode and the component is attributed to a change in the direction of the current flow; in the 60-150 A range the current was directed from the component to the electrode, whilst in the 300 to 1300 A range the current flowed in the opposite direction. In Fig.4 the influence is graphed of the length of the arc gap for a Fe-Fe arc. In Fig.5 the influence is graphed of the ambient medium on the thermal balance of a Fe-Fe arc.

Ionized Stream of an Electric Arc for Heating

to 0.24 times the voltage-current product for the arc in the channel. Fig 3 shows the heating power (cal/sec) and efficiency as functions of the rod-to-ring distance (curves a and b), respectively). Efficiency is practically independent of this distance. The effective heating power is, to a first approximation, directly proportional to current (Fig 4a) but efficiency decreased (Fig 4 b). Fig 5 shows the heating power and efficiency as functions of argon flow (a and b, respectively): efficiency increases to 30 - 32% at a flow of 500 - 600 litres/hr, remaining at this value at higher flow. With 86% helium - 14% argon mixture the heating power was almost doubled that with pure argon, but efficiency remained practically unchanged; neither heating power nor efficiency was appreciably affected by replacing the tungsten electrode by carbon or by changing electrode diameter in the range 1.3 - 3 mm (table). The authors point out that the ionized stream can provide a heat flow approximating to that obtained by direct arc

TITLE:

Arc Plasma Jets as a Heat Source During Material Treatment

PERIODICAL:

Svarochnoye proizvodstvo, 1959, Nr 9, pp 1-4 (USSR)

ABSTRACT:

The article presents a method and design of a device to produce plasma jets. These shall be used as an independent heat source. The author also discusses in which cases they can be used in the treatment of different metals. In the active spots of the arc the high current density causes a fast heating and evaporation of the electrode material. The vapors, which are ionized in the area near the electrode, move with high speed from the electrode and form a brightly luminous jet, with a length up to 15-20 mm and more (Fig 1). The spectrum research was made by N. N. Sobolev, who showed, that the jet mainly consists of ionized atoms of the electrode material. The speed of jet corpuscles can reach 300-1000 m/sec. The temperature of the jet is about

Card 1/3

SOV/135-59-9-1/23

## Arc Plasma Jets as a Heat Source During Material Treatment

10,000°C at a distance of 2-3 mm from the electrode end, and about 6,000°C at a distance of 6-8 mm. There is always a considerable ionization of the atoms. Fig 2 shows the heat and mechanic characteristics of the jet within an argon atmosphere. Fig 3 shows two principal schemes of a device which produces arc plasma jets. In the Institut metallurgii AN SSSR (Institute of Metallurgy of AS USSR) four types of arc plasma jet producing devices were constructed: IMET-101 for the research of the devices energetic parameters, IMET-102 for use by hand (Fig 6), IMET-103 and IMET-104 for machine-driven use. Fig 7 shows how the heat power, effective efficiency and arc voltage depend: 1) on the nozzle arrangement on the surface which is to be heated and 2) from the cavity of the core electrode. The authors state that there are great possibilities for using an arc plasma jet for the welding of sheet materials, including heat resistant metals. Especially efficient is the use of plasma jet for soldering. There are 4 photographs, 1 drawing, 2 graphs, 1 table and 4 Soviet

**TITLE:** Investigating the cutting with arc plasma jet singled out from a  
cathode flame

**PERIODICAL:** Svarochnoye proizvodstvo, no. 5, 1961, 1-4

**TEXT:** A plasma jet is used for severing and surface-planing of different materials. The plasma jet is produced by discharge of an arc excited between tungsten electrode 1 and water cooled copper nozzle 2 (Fig. 1), (Ref. 1, 2). Gas is blown through the nozzle along the cathode flame which is ionized and leaves the nozzle in the form of a bright plasma jet attaining temperatures of 10,000 - 15,000°C and more. Of the two existing methods of plasma cutting, namely with the use of a plasma arc, singled out from or coinciding with the cathode flame, the authors selected the second method to investigate the heat characteristics and the cutting properties of the plasma arc. The information includes the designing of a plasma torch developed for the cutting of a number of materials. The efficiency of the cutting process depends considerably on the effective

Investigating the cutting with arc plasma ...

power and the cutting properties of the plasma jet which are determined by the arc current and voltage, gas consumption and composition, length and diameter of the nozzle channel and the distance of the nozzle from the surface to be cut (Fig. 2 and 3). Maximum efficiency of plasma arc cutting is assured by maximum possible welding current and arc voltage, least possible distance of the nozzle from the surface of the sheets to be cut, minimum length of the nozzle channel, and optimum gas consumption and nozzle diameter. The cutting rate can be increased by using gases or gas mixtures of high ionization potentials. Comparison data on the cutting rate by various methods are given in a table. Plasma arc cutting with a jet singled out from the cathode flame can be employed for cutting various non-electric conducting materials, such as refractory bricks, concrete, granite, carborundum etc. The process can be performed either manually or automatically. According to data submitted by engineer V. P. Norenko of Kramatorsk at the Moscow Welding Conference in March 1960, the method assures satisfactory properties of the cut when preparing stainless steel sheets for welding. On the basis of DMT-104 torch, an improved design - the MM3T-106 (DMT-106A) torch was developed in 1960, intended for automatic and manual cutting, at 300 - 350 amp current and 15 kw maximum power. The water-cooled adapter contains a screwed-in nozzle with a conical contact surface and threaded lower section (Fig. 6).

Rapid determination of small amounts of arsenic in organic material. A. V. Bobakov. *Voprosy Patents* 8, No. 4, 69-72(1980); cf. C. A. 28, 6699. A slightly modified app. of Sanger and Black (C. A. 2, 2352) was used. In the set-up all connections are ground in. Instead of oxygen, a slash of  $H_2$ , test paper is placed particularly to the generated gas flow, against the lower end of the exit tube having an internal diam. of 8 mm. (cf. C. A. 26, 8253). The obtained stain is compared with stains produced by standard test tubes. 1 tube with standard stains wrapped in black paper and kept in a desiccator can be used for about 1 mo. Amts. of 1-15  $\mu$  can be determined. After a certain exposure the entire procedure, including digestion of org. matter, takes 1.5 hrs.

The heating curve method of thermal stability the decomposition of certain complex compounds of platinum. A. V. Nikolsky and A. M. Rubinshteyn. *Russ. Chem. Rev.* 1958, 27, 94 (in English, 1958). The heating curve method can be employed successfully for studying the thermal stability of complex compounds that have identical ligand spheres, but different anions. The heating curves of chloroplatinic acids,  $[Pt(NH_3)_4Cl_2]Cl$  (I),  $[Pt(NH_3)_4Cl_2]Cl_2$  (II), and  $[Pt(NH_3)_4Cl_2]Cl_3$  (III) are very similar. These heating curves show that (1) the thermal stability of platinumous compounds depends to a considerable extent on the outer sphere and obeys the rules found for other compounds (the stability of a complex compound is proportional to the radius of the anion; I is most stable, III is least so, and II the least); (2) the existence of  $[Pt(NH_3)_4]^{2+}$  has been established; (3) a splitting of 1 mol. of  $[Pt(NH_3)_4Cl_2]Cl$  from II took place between 170 and 185° with the conversion of II into a mixt. of  $[Pt(NH_3)_4Cl_2]Cl$  (V) (70%) and  $[Pt(NH_3)_4Cl_2]Cl_2$  (VI). This was expressed on the heating curve by 2 endothermic effects. The thermograms of V, of VI and of their mixt. (1:1), of  $[Pt(NH_3)_4Cl_2]Cl_2$ ,  $[Pt(NH_3)_4Cl_2]Cl$ , and of II were investigated. V begins to decomp. at 245°, has a break at 250° and the decomp. is completed at 260-265°. All effects are endothermic. I is more stable than V. VI is stable up to 220°, where it has a break. The decomp. ends at 235°. The mixt. of V and VI which is formed from the decomp. of II also begins to decomp. at 245° and completes the decomp. at 265°. The mixt. obtained from the catalytic decomp. of II begins to decomp. at a higher temp. than do

its components (265°). The curve has markedly defined plateaus and is characterized by a polythermic region of decomp. which is completed at 425-430°. On the basis of the heating curve I and II conclude that the product obtained during the catalytic decomposition of II is to be regarded as a chloro complex. The combination of 2 chloroplatinous produces a complex which is more thermally stable than any the initial substances. Four references. W. R. Hess

DECLASSIFIED

Investigations of sparingly soluble crystalline precipitates. I. Magnesium hydroxide. A. V. Nikoduy, *J. Applied Chem. (U.S.S.R.)* 20, 187-201 (1947) (in Russian). --(1) The filterability of Mg(OH)<sub>2</sub> pptd. expressed by the filtration coeff.  $k$ , defined by  $Q = kSH/t$  ( $Q$  = ml filtrate,  $S$  = surface area in sq. cm,  $H$  = pressure in cm. H<sub>2</sub>O,  $t$  = thickness of ppt. layer in cm,  $t$  = time of filtration in sec.,  $k$  in cm<sup>2</sup>/sec.), was found as a function of the total time  $\tau$  (in hrs.) of drop by drop pptn. of a 10% MgSO<sub>4</sub> soln. with 10% NaOH. The curve of  $k$  against  $\tau$  shows 3 branches: an initial horizontal portion of low  $k$  at  $\tau$  up to 0.5 hrs., an ascending branch and a final horizontal portion of const. limiting  $k$  of the order of  $10^{-4}$  cm<sup>2</sup>/sec. from  $\tau = 2$  hrs. on; an analogous curve, and  $k$  values of the same order, are found for the pptn. of 10% MgCl<sub>2</sub> with Ca(OH)<sub>2</sub>. The same limiting  $k$  was found in expts. in which a 10% MgSO<sub>4</sub> soln. was pptd. dropwise with 9 portions of NaOH, each portion taking 30 min., with 30-min. pauses between portions; hence, the limiting filterability is not increased by the chance of coarsening of grains provided by the rest periods. Thus, it is demonstrated that growth of crystals takes place only on actual addn. of precipitant, not between addns. Along the 1st branch of the  $k(\tau)$  curve, the time elapsing between drops (0.25 sec. at  $\tau = 0.25$  hrs. is too short for the pH around the drop to decrease to 0.4 of Mg(OH)<sub>2</sub>, and crystal growth can only be very slow; conditions become increasingly favorable along the 2nd branch but only from  $\tau = 2$  hrs. upwards is the time interval between drops (= 2 sec.) sufficient for each drop to spend itself completely before the next drop is added. The factor detg. max. filterability is thus shown to be the time between consecutive drops of the precipitant. (2) The rate of settling, expressed by plotting  $\tau =$  height of ppt. height of liquid, against time, at various  $\tau$ , parallels the behavior of  $k$ : at a total height of 3.7 cm., with  $\tau = 0.5$  hr.,  $\tau$  reaches 2 in about 1 1/2 hr. and  $\tau = 1$  after 2 1/2 hrs.; with  $\tau$  not more than 2 hrs., the limiting  $\tau = 0.5$  hrs. (complete settling) is reached in about 1/2 hr. or less. Thus,  $\tau = 2$  hrs. is critical in both settling and in filtration. (3) In

pptn. with excess NaOH, in more concd. solns. (23% MgSO<sub>4</sub> pptd. with 31.8% NaOH), the final  $k$  is considerably lower ( $5 \times 10^{-4}$  at  $\tau = 2$  hrs.) than the normal limit; the peptizing effect of NaOH was also shown on a limit, the peptizing effect of NaOH, overnight treatment ppt. having attained  $k = 1 \times 10^{-4}$ . Even with 32% NaOH caused  $k$  to fall to  $3.4 \times 10^{-4}$ . Even with 32% NaOH soln. with MgSO<sub>4</sub> resulted in a slow pptn. of a NaOH soln. with MgSO<sub>4</sub> resulted in a slow pptn. settling to only  $\tau = 4.6$  in 24 hrs. (i.e., much slower than when MgSO<sub>4</sub> is pptd. with NaOH in  $\tau = 0.25$  hrs.); this, again, confirms the peptizing effect of NaOH. (4) Inclusion of SO<sub>4</sub> in the Mg(OH)<sub>2</sub> ppt. increases somewhat with increasing slow test of pptn.; thus, in the 9-step pptn. with 30-min. pauses, the ppt. after washing until disappearance of SO<sub>4</sub> (reactive), still retains 4-0.25% SO<sub>4</sub>. In the reverse case, in the  $\tau = 2$  hrs. expt., 0.40% SO<sub>4</sub>. In the reverse case, of NaOH with MgSO<sub>4</sub>, the ppt. contained 0.13% SO<sub>4</sub>. In Mg(OH)<sub>2</sub> pptd. from MgCl<sub>2</sub> with Ca(OH)<sub>2</sub>, SO<sub>4</sub>. In Mg(OH)<sub>2</sub> pptd. from MgCl<sub>2</sub> and washed rapidly  $\tau = 1$  hr., left standing for 2-6 hrs. and washed rapidly until disappearance of Cl<sup>-</sup>, the Ca content was of the order of 0.1%; after 2 days standing, Cl<sup>-</sup> could no longer be washed out and the Ca content was 0.16%. The granulometric compn. of the ppt. was 0.16% microscopically and by sedimentation. By both methods, increasing  $\tau$  results in increasing heterogeneity of the ppt. and in a shift to smaller particle size,  $\tau$ . (by microscop. count)  $\tau = 1$  hr., 1.6% of grains, percent of grains of 1.0-6.4, 6.4-12.8, 12.8-19.2, 19.2-25.6, 25.6-32.0, 32.0-38.4, 38.4-44.8, 44.8-51.2, 51.2-57.6, 57.6-64.0, 64.0-70.4, 3074. COMPOSITE STUDY OF PRECIPITATES. A.V. Akhalev and M.P. Akentukh (J. anal. Chem. USSR, 1952, 7, 21-33). The determination of characteristics such as the coefficient of filtration and the rate of sedimentation are described and exemplified in the case of ppt. of  $\text{CaCO}_3$ ,  $\text{Mg}(\text{OH})_2$ , and  $\text{Al}(\text{OH})_3$ . Numerical values can be given as a result of simple experiments under various conditions of ppt. and filtration, and the data now presented and those to be obtained later for other ppt. should be valuable for characterizing ppt. for analytical and preparative purposes.

NIKOLAYEV, A.V.

✓ Differential thermal microanalysis. A. V. Nikolayev and  
 A. M. Simbina. *Russkaya Khimiya*, **1961**, 127-128 (1961). *Abstr. Week*  
 1961, **2**, 127-128 (1961). For samples of only a few mg,  
 the usual thermocouples are too thick and cannot detect  
 small thermal effects. A direct recording of the heating  
 curves on photographic paper (Kuzashov differential gal-  
 vanometer) is possible if the rotation of the recording drum  
 is considerably accelerated, and the heating rate increased  
 to 100°/min. Berg and Rosenzskaya (C.A. 43, 324) de-  
 scribed a very useful microapp. with a metal heating block  
 (up to 1000°). Heating and differential thermal analysis  
 curves are shown for In<sub>2</sub>O<sub>3</sub>, 20%O<sub>2</sub>B<sub>2</sub>O<sub>3</sub>, 111%O, Perron's  
 salt,  $\alpha$ -PbCl<sub>2</sub>·2NH<sub>3</sub>, and Na<sub>2</sub>CO<sub>3</sub>. Inyoite shows 2 endo-  
 thermic effects, and one exothermic effect, in excellent agree-  
 ment with data by macro methods. Also the conversion  
 of cis  $\rightarrow$  trans complex, e.g. in Perron salt, are observed by  
 the micromethod, although somewhat displaced in temp.  
 The entire course of the microcurve corresponds nearly to  
 the complete equil. conditions. The decompos. of Na<sub>2</sub>CO<sub>3</sub>  
 to Na<sub>2</sub>O, and the transition of the metastable Na<sub>2</sub>CO<sub>3</sub> to  
 the stable modification are clearly observed in both types of  
 curves. W. Hill

**"Extraction of Inorganic Substances With Organic Solvents," by  
Prof A. V. Nikolayev, Khimicheskaya Nauka i Przemyslennost',  
Vol 1, No 5, Sep/Oct 50, pp 548-554.**

After pointing out that the method of solvent extraction was introduced into inorganic chemistry and technology as a result of its successful application in nuclear energy work in connection with the necessity of producing highly purified substances and eliminating splinter elements, the author outlines the advantages of this method and suggests possible applications. He says that, contrary to the opinion held by many investigators, uranium is not the most easily extractable element, at least as far as extraction with ether is concerned. He suggests that extraction methods be investigated with the purpose of applying them in the concentration and purification of rare and dispersed elements and says that these methods are already being used with good results in the production of semiconductor materials.

In the main section of the article, the author discusses the mechanisms of extraction, using a classification proposed by V. I. Kuznetsov, who postulates three principal mechanisms: extraction in the form of oxonium salts, extraction based on the loss of affinity to water, and extraction on the basis of "physical distribution." Nikolayev presents in this section a considerable amount of data on extraction processes, including separation of thorium from actinium by extraction with thenoyltrifluoroacetone, separation of promethium from yttrium with tributylphosphate, extraction of uranyl nitrate with diethyl ether, interference produced by different ions in the extraction of uranium with diethyl ether, and separation of uranium from thorium by extraction with ether as affected by different salting-out procedures.

In conclusion the author says that extraction methods are being successfully used in the production of rare and radioactive elements; that detailed experimental investigation makes it possible to solve successfully from the technical and economic standpoint simpler problems such as the separation of Fe from Co and Ni, of Mo from W, of Sb from As, etc.; and that much can be expected from the development of extraction methods combined with the application of cheap extraction agents and complex-formers, extraction with boric and phosphoric acids being particularly promising. A bibliography which consists of 4 USSR references and 11 non-USSR references is appended to the article.

"On the Contemporary Status of the Theory of Salts" by Prof. A. V. Nikol'skiy  
Moscow, Khimicheskaya Nauka i Promyshlennost', Vol. 2, No. 6, Nov/Dec 57,

pp 670-676  
Distri. 2843/4B3d

This article reviews industrial applications of naturally occurring salts, 13  
the physical characteristics, and the use of  
the metal to their properties and their  
characteristics, the amount of energy  
from the side of  
semiconductor technology is discussed  
ionic crystalline salts on the other hand, the percentage of  
covalent bonds becomes substantial already in the ionic lattice of calcium  
sulfide and is very significant in sulfides, selenides, and tellurides. For this  
reason, semiconductor properties are exhibited by salts of the last mentioned class.  
of this class are being investigated intensively at present from this stand-  
point. The following elements are mentioned as semiconductors including  
to the valency of the metal ion, a special case

...the contemporary situation of the...  
 ...method of refining, in which the volatility of the iodide is of definite significance,  
 is being applied to an increasing extent in metallurgy. In addition to having  
 a low melting point and being volatile at low temperatures, salts with  
 ...exhibit the important property of a definite increase  
 ...that they can be extracted...  
 ...fol 1, 1955, pp. 107  
 In the last section of the article, i.e., that on the use of salts as  
 solvents, work on the solubility of various salts in water at high pressures  
 and temperatures is discussed...  
 ...the iodide...

... with fused fluorides has been used for the separation of plutonium and of fission elements from irradiated uranium.

... simple crystals are now being used for a very important application, as sensitive elements of scintillation counters. Examples of this type of application are given in the text. The author furthermore states that lithium salts are used in neutron counters and sodium iodide activated with thallium in gamma-radiation counters; gamma-radiation counters of this type are more sensitive than Geiger-Mueller counters, reaching a sensitivity of that of beta-counters.
