Authors : Nikol'skiy, G. V., and Soin, S. G.

Title : On the biological bases of salmon breeding in the Amur basin

Periodical : Priroda 43/4, 52-53, Apr 1954

Abstract : An account is given of a study of the characteristics of seven varieties of salmon, from which two were selected, the hump-backed salmon and the Siberian salmon, as being the ones maturing more rapidly. A detailed description is given of the biological factors involved in the hatching and raising of salmon and of the equipment installed in the Amur river for this purpose and the method of its operation. Illustrations; tables.

MYKOLISKII, G. V.

"Some Problems Concerning the Biological Foundations of Salmon Fishing in the Far East," Oceanographic Research of the Northwestern Part of the Pacific Ocean, Moscow, Izd-vo AN USSR, 1958. (Fluctuations in the quantity of salmon depends on climatic conditions. The article stresses the need to improve conditions for natural spawning in rivers and estuaries, and, whenever necessary, to organize spawning farms.)

COVERAGE: This collection of articles reports the results of observations made in the Pacific by the Institute of Oceanology of the Academy of Sciences, USSR. In 1949, the Institute launched a systematic five-year program of scientific exploration of certain hydrographic peculiarities of the Soviet Pacific area. The operations were carried out as a "Complex Oceanographic Expedition," using the motorboat 'Vityaz' as its base. The Expedition worked in collaboration with the Hydrographic Institute of the Soviet Navy (VMS), the Pacific Institute of Piscatology and Oceanography and some 40 other institutes of the Academy of Sciences. Between 1949 and 1954, 18 trips were made, covering about 130,000 miles. Among the subjects of direct concern were: meteorology, hydrology, Oceanography, hydrochemistry, sedimentation, geography of the littoral, geology and contours of the sea bottom, fauna, plankton, microbiology, and gravimetry. Twenty-eight authors contributed to the collection which consists of 27 articles.

AUTHOR: Mikol'skiy, G. V., Corresponding Member 50-58-4-11/44
of the AS USSR

TITLE: Meeting of the International Council for Marine Research (Sessiya mezhdunarodnogo soveta po izucheniyu morey)

PERIODICAL: Vestnik Akademii Nauk SSSR, 1958, Vol. 28, Nr 4,
pp. 69-70 (USSR)

ABSTRACT: This Council at present includes 16 countries. The Soviet Union was accepted in 1955. From September 30 till October 8, 1957 the 45th annual meeting of this Council took place at Bergen (Norway). The Soviet delegation consisted of N. K. Myrukov, T. F. Dement'yev, N. A. Dmitriev, A. Ye. Kriss, I. I. Lagunov, V. A. Lednev, M. N. Lichev, Yu. Yu. Marti, G. V. Mikol'skiy, M. N. Fedosev. Before the meeting a symposium on problems of the primary capacity of the sea as well as a special discussion on the protection of bottom fishes in the Baltic Sea. The majority of the reports was devoted to the problems

Card 1/3

Meeting of the International Council for Marine Research 30-58-4-11/44

of the conditions of the stocks of industrial fishes and the measures for their protection. The Soviet scientists were interested in data on the conditions of the swarms of Atlantic-Scandinavian herrings. On these problems the Soviet delegation submitted three reports: Ju. Ju. Marti on "The Influence of Industry on the Stocks of Herrings"; M. N. Lishov on "The Dynamics of the Quantity of the small herring of the East Baltic Sea", and on the Selectivity in the Drag-Net Industry in the East Baltic Sea". N. A. Maslov and Yu. Yu. Marti reported on the stock of cod-fish in the Barents Sea. A number of reports was dealing with methodological and terminological problems. D. V. Radakov and D. S. Nikolajev (USSR) reported on the change of the effectivity of fishing equipment when ravenous fish are present in the zone of catching. I. I. Lagunov and V. V. Arbelev (USSR) reported on the influence of a fish haul at the GES, Tulom, on the salmon swarm. The next, 46th meeting was decided to take place in Copenhagen on September 29, 1958;

Card 2/3

Meeting of the International Council for Marine Research 30-98-4-11/44

before that meeting it is intended to hold a symposium on salmon breeding problems. In the spare time research ships and museums were visited. The author considers the participation in this meeting very fruitful.

TITLE: Spectroscopic method of measuring proton energy in plasmoids

SOURCE: Diagnostika plazmy (Plasma diagnostics); sb. statey. Moscow, Gosatomizdat, 1963, 2-8

TOPIC TAGS: plasma physics, plasmoid, proton, Stark effect, energy distribution, plasma confinement

ABSTRACT: A spectroscopic method is proposed for the measurement of the energy distribution of protons in plasmoids. It is free of some of the shortcomings of existing methods in that it does not require that the plasmoid be taken out of the working volume to the analyser. The bremsstrahlung and recombination-radiation spectra of the plasmoid are investigated in this method directly, and the proton energy from a Penning ion source is also measured. The procedure can be used to measure the distribution of the proton energy in plasmoids having a density exceeding 10^{13} cm^{-3} and an energy exceeding 100 eV. The tests were made with a continuous Penning discharge in hydrogen and in a longitudinal magnetic field reaching

Card 1/3

ACCESSION NR: A74025287

2500 Ge, at source voltage up to 2 kV. The spectral distribution of the radiation intensity near the H_β line with $\lambda = 4,861 \text{ \AA}$ was measured. It is shown that the density of the ions in the plasmoid can be determined if the exact values of the charge exchange cross sections at the excited levels are known. The plasma density can also be estimated from the Stark broadening of the line. The experimental maximum in the velocity distribution corresponded to an estimated proton energy 30 MeV. The maximum shifts towards higher energy with increasing voltage and with decreasing pressure. Orig. art. has: 1 figures and 10 formulas.

TITLE: Macroscopic plasma instability in a reflex discharge

SOURCE: Zhurnal tehnicheskoy fiziki, v.34, no.4, 1964, 590-596

TOPIC TAGS: plasma, plasma instability, reflex discharge plasma, PIG Reflex, anomalous plasma diffusion, holium plasma

ABSTRACT: Plasma stability and diffusion were investigated in a cold-cathode reflex discharge in a longitudinal magnetic field (PIG Reflex). The discharge took place in a glass tube 5 cm in diameter containing helium at pressures from 5×10^{-4} to 10^{-2} mm Hg. The aluminum electrodes were 44 mm in diameter. The cathodes were separated by 70 cm, and the anodes, provided with 36 mm openings, were mounted 8 cm from their respective cathodes. Potentials up to 2 kV were applied, and currents from 50 to 300 mA were obtained. The longitudinal magnetic field was uniform within 0.5% and could be varied up to 3400 Oe. The following diagnostic instruments or procedures were employed: simple probes; a double electric probe on the axis; 3 cm microwave transmission measurements; electron temperature measurement by observation

Card 1/2

ACCESSION NR: AP4028943

of the intensity ratio of the He II 4686 Å to He I 4921 Å lines; luminous intensity measurements. Electron densities and temperatures of the order of $5 \times 10^{11} \text{ cm}^{-3}$ and 20 eV, respectively, were observed. It was found, in agreement with the observations of J.F.Bonnal, G.Briffod and C.Kanus (Phys.Rev.Let.6,665,1961) that the ion current to the wall of the tube reached a minimum at a certain critical value of the magnetic field and increased in stronger fields. The value of the critical magnetic field increased with helium pressure from about 500 Oe at 10^{-3} mm Hg to 1200 Oe at $5 \times 10^{-3} \text{ mm Hg}$. The electron temperature and density on the axis reached maxima at the critical magnetic field. A radial electric field developed in the plasma at the critical magnetic field and increased with further increase of the magnetic field. Values over 60 mV/cm were observed. Macroscopic motion of the plasma column was observed by rotating mirror time-resolution photography. The column developed helical structure at magnetic fields above the critical, and pulsated at frequencies from 200 to 800 cycles/sec. Density oscillations at frequencies from 20 to 50 kilocycles/sec were observed by microwave and probe measurements. The electron temperature and the luminous intensity decreased monotonically with increasing distance from the axis, and the electron temperature had two maxima, one on the axis and one in the outer portion of the column. The increased ion diffusion at fields above

Card 2/3

ACCESSION NR: AP4028943

the critical field is ascribed to the macroscopic motion of the column. It is suggested that these oscillations were not observed by Bonnal, Briffod and Manus (loc. cit.) because of their very low frequency. The rotation of the column is ascribed to azimuthal drift in the crossed radial electric and longitudinal magnetic fields. The origin of the radial electric field is not understood; several possibilities are briefly discussed. The failure of F.Chen and A.Cooper (Phys.Rev.Let.9,333,1962) to observe the increased diffusion is ascribed to the stabilizing influence of the metal walls of their discharge chamber with respect to the development of large amplitude magnetohydrodynamic instabilities. "In conclusion, the authors consider it their duty to express their gratitude to B.B.Kadomtsev, V.T.Tolok and Ya.B.Faynberg for discussing the results, and to I.Yu.Adamov and V.I.Komissarov for assistance in the work." TITLE: Damping radiation in the infrared region of the spectrum of plasma under electrofreeless induction discharge

SOURCE: Optika i spektroskopiya, v. 19, no. 5, 1965, 674-679

TOPIC TADS: plasma diagnostics, hydrogen, germanium, photoresistor, IR radiation

ABSTRACT: The authors investigated the damping radiation in the infrared region of the spectrum of an electrofreeless induction discharge of hydrogen. The damping radiation in the region of 1.8 - 9.5 μ k wave length was registered by a germanium photoresistor operating under the temperature of liquid nitrogen. The ionity of the plasma was determined based on the results obtained from measuring the temperature of plasma electrons and the intensity of damping radiation. The proposed method could be used for diagnostics of a dense plasma. The authors express thanks to A. F. Plotnikov and G. N. Zhizhin. Orig. art. has: 6 figures and 8 formulas.

$\sim 1 \times 10^{14} \text{ cm}^{-3}$ and the electron temperature was 4 to 4.5 eV. The velocity of the fast component of a bursts was $1.4 \times 10^7 \text{ cm/sec}$. This was followed by a slower "tail". The collision of two plasma bursts led to an increase in the intensity of all spectrum lines and the appearance of lines that were not observed in single bursts. Velocity measurements performed with the photoelectric instrument using the H I 4861, C I 4371 and C II 4267 lines showed that both the carbon ions and the hydrogen atoms moved more rapidly than the carbon atoms. The presence of excited ions in the plasma burst at a considerable distance from the source is discussed, and it is suggested that these are continually formed by a charge exchange mechanism. The ion temperature was determined from the Doppler broadening of the C II 4267 line. Oscillation of the plasma bursts was found to be accompanied by an increase of the ion temperature. After brief discussion it is concluded that the strong interaction between plasma bursts observed in this and the previous work can be accounted for by Coulomb interaction. In conclusion, the authors express their gratitude to L. V. Braginskii, A. P. Polgov and A. A. Kutsyn for technical assistance in performing the work." Orig. art. has: 6 figures.

TITLE: Instability of a plasma discharge with oscillating electrons. 2. Anomalous diffusion of plasma

SOURCE: Zhurnal tekhnicheskoy fiziki, v. 35, no. 8, 1985, 1401-1404

TOPIC TAGS: plasma instability, plasma oscillation, helium plasma, electric discharge, electron oscillation, electron reflection, plasma diffusion, plasma magnetic field

ABSTRACT: The authors have investigated the stability and anomalous diffusion of the plasma of a high voltage PIG reflex discharge with the apparatus described in the preceding paper (ZhTF, 35, 1394, 1985; see abstract AP5020724). In addition to the measurements described in the preceding paper, measurements were made of the charged particle flux to the wall of the chamber, using a double probe, and the plasma column was observed with a rotating mirror. The charged particle flux at first decreased with increasing magnetic field, but at a certain critical field strength the flux began to increase with increasing field strength. The critical

Card 1/3

L 2493-66

ACCESSION NUR: AP 5020725

field was that for transition from region II to region III discussed in the preceding paper. When the magnetic field increased through the critical value the plasma density suddenly decreased, the microwave noise suddenly increased, and oscillations of the plasma column were observed with the rotating mirror. The critical magnetic field strength in helium plasmas increased with rising gas pressure from 1000 Oe at 10^{-4} mm Hg to about 1600 Oe at 2×10^{-3} mm Hg. There was no anomaly in the electron temperature at the critical field. These results are compared with the theory of F.Hoh (Phys. Fluids, 6, 1184, 1963), and it is shown that the magnetic field strength at onset of anomalous diffusion is an order of magnitude less than the theory predicts. It is suggested that a turbulent state with a broad spectrum of low-frequency oscillations may arise from the interaction between the plasma and the oscillating electron beam. The authors hope further to pursue their studies of these phenomena. "In conclusion, the authors express their gratitude to X.D.Sinel'shikov for discussing the results and to B.I.Kononenko and M.Yu.Mazulchenco for assisting with the work." TITLE: Bremsstrahlung of a θ-pinch plasma in the infrared spectral region 55 C71

SOURCE: AN UkrSSR. Magnitnyye lovushki (Magnetic traps). Kiev, Naukova dumka, 1965, 198-206

TOPIC TAGS: bremsstrahlung, plasma pinch, electron temperature, plasma density, IR spectrum

ABSTRACT: The authors review the various methods used for determining the parameters of a plasma from the intensity of Bremsstrahlung. If the receiver design does not permit wavelength adjustment, the absolute intensity of the Bremsstrahlung in the plasma is measured in a definite wavelength range and an independent method is used for determining one of the parameters of the plasma, e. g. the electron temperature, and its variation with time. These data are then used as a basis for determining the plasma density and its variation. The possibilities of using this type of a receiver for plasma diagnosis are discussed. Experiments were conducted which showed that the continuous radiation of a plasma in the near infrared region may be measured simultaneously with the electron temperature to determine the density of the plasma and its

Card 1/2

L 23569-66

ACC NR: AT6008860

variation with time. The sensitivity of this method may be improved by reducing the band of the preamplifier of the recording system and by making the measurements on a plasma in which slower processes take place since this would allow covering a wider density range.
