TITLE: Thermodynamic Investigation of Lower Tungsten Chlorides
(Termodynamicheskoye issledovaniye nizshikh khloridov tunganiza)

PERIODICAL: Vestnik Leningradskogo universiteta Seriya fizika i khimi.
1959, Nr. 1, pp. 120-131 (USA)

ABSTRACT: For these investigations two unites WCl_3 and WCl_4 were used,
which were obtained from WCl_6 by reduction with hydrogen. WCl_3
was obtained from the decomposition of WCl_4 in vacuum at 100°C
(Refs. 1,4). The three tungsten chlorides were analyzed by the
hydrolysis method that had been worked out by the authors in
their work as per reference 2. The vapor pressure of WCl_3 was
determined in the temperature range of 150-800°C. The values of
the saturated and unsaturated vapor pressures are given in
the table 1. From the latter the molecular weight of WCl_3 in the
vapor phase was determined by the aid of the Raoult-Labeyen
equation. In this article, the presence of the Raoult-Labeyen
equation. In this article, the presence of the Raoult-Labeyen

Soviet Science

Thermodynamic Investigation of Lower Tungsten Chlorides

was detected in the vapor and the thermal, kinetic characteristics of dipolymerization, proceeding according to the scheme $(WCl_4)_2 \text{vapor} \rightleftharpoons 2(WCl_2)_{\text{vapor}}$, were calculated. The total pressure and the optical density of WCl_4 in the temperature range of 150-500° were measured (the corresponding results are given in Table 1). These measurements led to the assumption that tungsten tetrachloride is disproportionated according to the scheme $4WCl_4 \rightleftharpoons WCl_2 + 3WCl_4$. For this purpose the characteristic $(WCl_4)_2 \text{vapor} \rightleftharpoons 2(WCl_2)_{\text{vapor}}$ was determined by approximation. From the characteristics were determined by approximation of the total pressure of the saturated vapor of WCl_4 and the thermodynamic characteristics of sublimation and of evaporation. It was found together with the melting and boiling points that it is further found that WCl_4 is likewise disproportionated according to the scheme $3WCl_4 \text{solid} \rightleftharpoons WCl_2 \text{solid} + 4WCl_4$.

TITLE: Dependence of the Disproportionation Pressure of Low Tungsten Chlorides on the Composition of the Solid Phase
(Zavisimost' uprugosti disproportsirovaniya nizshikh khloridov vol'frama ot sostava tverdogo fazы)

PERIODICAL: Vestnik Leningradskogo universiteta. Seriya fiziki i khimii,
1959, Nr 2, pp 79-82 (USSR)

ABSTRACT: The thermodynamic characteristic of the disproportionation of WCl_4 and WCl_2 to the final products WCl_3 and metallic W , respectively, is only possible if in the existing solid phase no interaction of these substances occurs. In this connection, investigations of the dependence mentioned in the title were carried out here. WCl_5 was used as initial product for the preparation of the low tungsten chlorides. WCl_4 was obtained by repeated reduction (Ref. 1) in the flowing current, and WCl_2 by disproportionation of the latter. The initial

Card 1/3

Dependence of the Disproportionation Pressure of SOV/54-5-1-11/2:
Low Tungsten Chloride on the Composition of the Solid Phase

mixture used for the investigation, which contained WCl_5 , WCl_4 and WCl_2 and also metallic W, was analyzed by pyrolysis (Ref 6). The results are indicated in table 1. The steam pressure over the mixture was statically determined by quartz-diaphragm zero manometer (see Refs 7, 8). The total pressure of the steam over a $\text{WCl}_5 + \text{WCl}_4$ mixture with different ratios Cl:W at different temperatures (Table 2) shows that the isothermal line of the steam pressure at the interval 4.6-4.0 Cl:W assumes the values of the isothermal line of the disproportionation pressure of the pure WCl_4 . This statement shows that there is a certain limited solubility between WCl_5 and WCl_4 . The insolubility of the mentioned substances in one another is determined by the pressure of the disproportionated steam over the $\text{WCl}_4 + \text{WCl}_2$ mixture at various ratios Cl:W (Table 3) which shows perfectly horizontal isothermal lines. Table 1 shows the disproportionation

Card 2/3

Dependence of the Disproportionation Pressure of SOV/54-59-2-11/24
Low Tungsten Chlorides on the Composition of the Solid Phase

pressures of the steam over a mixture of WCl_2 + metallic W.

It shows that there is a certain interaction between the mentioned substances. A comparative X-ray investigation showed that WCl_2 exists in the range 2.0-1.7, and some unknown lines can be observed beside the lines of the latter; in the range 1-0, there are only the lines of pure metallic tungsten beside some unknown lines. Therefore, the determination of the disproportionation scheme of the mixture WCl_2 is rendered very difficult by the existence of a solubility of WCl_2 and W in one another. There are 1 tables and 8 references, 3 of which are Soviet.

The Thermographical Investigation of the Systems $WCl_6 - WO_3$,
 $WCl_6 - WO_2$, $WCl_6 - MoCl_5$ PERIODICAL: Zhurnal neorganicheskoy khimii, 1959, Vol 4, Nr 9, pp 2062-2066
(USSR)

ABSTRACT:

Tungsten oxychlorides are only occasionally described in publications. However, as tungsten forms a considerable number of oxides and chlorides, a corresponding number of oxychlorides may be expected. The equipment used in the investigation is schematically drawn in figure 1. One of the thermograms drawn by means of two M-21 reflecting galvanometers is given in figure 2 as an example. A scheme of the electric furnace is shown in figure 3. Figure 4 represents the melting-point diagram of the system $WCl_6 - WO_3$. From this it is evident that two oxychlorides are formed in the system $WOCl_4$ and WO_2Cl_2 . From the melting-point diagram of the system $WCl_6 - WO_2$ (Fig 5) three hitherto unknown oxychlorides were deduced:

TITLE: Determination of Saturation Vapor Pressure and Molecular Weight of Tungsten Pentabromide

PERIODICAL: Zhurnal neorganicheskoy khimii, 1959, Vol 4, Nr 10,
pp 2185-2188 (USSR)

ABSTRACT: There are only a few data available in publications on the bromine compounds of tungsten presently known (WBr_6 , WBr_5 , WBr_2 , WOBr_4 , WO_2Br_2). For this reason the authors report on tensimetric and thermographic determinations carried out on WBr_5 . $\text{W}(\text{CO})_6$ and Br_2 were used as initial products, which react under formation of hexabromide which was decomposed in vacuo at 250° to give WBr_5 and Br_2 . The tensimetric determination was carried out by means of a diaphragm-zero-manometer made of heat-resistant glass of the P-15 type. The temperature was measured by means of the PPTV-1 potentiometer. Table 1 gives the values obtained for the vapor pressure of WBr_5 between 170.4 and 384.4°C and 1 - 655 torr. In figure 1 the curve

Card 1/2

SOV/78-4-10-1/40

Determination of Saturation Vapor Pressure and Molecular Weight of
Tungsten Pentabromide

$\log P_{\text{saturated}} = f\left(\frac{1000}{T_K}\right)$ is shown. Between 230° and the melting point 295°C the values are below the calculated curve owing to impurities. The computed values for the vaporization and sublimation enthalpy and -entropy are in good agreement with the values obtained by L. Brewer (Ref 1), whereas the resultant melting- and boiling points deviate from the data available in publications. According to table 3 the analysis of WBr₅ gives a bromine content somewhat higher than that corresponding with the formula which is due to bromine adsorption. The values computed at 678.2°K and 742.2°K for the molecular weight of WBr₅ are likewise above the theoretical value. The presence of polymerized molecules is assumed. The solidification temperature obtained by tensimetry deviates a little from the value determined thermometrically (Table 5). There are 1 figure, 5 tables, and 6 references, 2 of which are Soviet.

TITLE:

On the Possibility of a Molecular Spectral Analysis of Vapors
Within a Wide Temperature Range

PERIODICAL:

Izvestiya Akademii nauk SSSR. Seriya fizicheskaya, 1959,
Vol 23, Nr 10, pp 1248-1250 (USSR)

ABSTRACT:

For the analysis of gas- and vapor mixtures it is possible to use the spectrum of this mixture in the visible-, in the ultraviolet-, or in the infrared range; whereas in the ultraviolet range the quantum energies are already so high that un-called for photochemical reactions occur, the strong influence exercised by temperature in the infrared range is a disturbing factor. For the investigation of a complex system in equilibrium, a spectroscopic method is, in any case, insufficient, because it is necessary, besides the partial component pressures, to know also the total pressure in the system. For their determination it is possible to employ any statistical method, but the membrane method (with zero manometer) was found to be especially useful. It was found that the amount of absorption is influenced by pressure, and

Card 1/3

On the Possibility of a Molecular Spectral Analysis of
Vapors Within a Wide Temperature Range 30V/48-23-10-30/39

still more by temperature. The temperature dependence of the amount of absorption has hitherto not been quantitatively investigated. Such an empirical method was the aim to be fulfilled by the authors. An investigation of the temperature-dependent variation of absorption and optical density in iodine vapors resulted in the formula $K_\nu = X_\nu T$, where X_ν

is a quantity which is independent of temperature. For its verification the system $N_2O_4 - NO_2 - NO - O_2$ was investigated in the range 18-480°C. Figure 5 shows the measured temperature dependence of the pressure p and of the optical density D . The diagram may be divided into 3 ranges: I) 18-100°C, equilibrium $N_2O_4 = 2NO_2$, II) 100-200°C, pure NO_2 , III) 200-480°C, equilibrium $2NO_2 = 2NO + O_2$. By using the Lambert-Beer law a formula may be derived for the determination of X_ν : $X_\nu = (D_\nu/p)(k/d)$. For a given frequency the following is thus obtained:

Card 2/3

On the Possibility of a Molecular Species Analysis of SOV/48-23-10-30/39
Vapors Within a Wide Temperature Range

$\chi_{5575} = 0.0194 \pm 0.0002$. Similar investigations were carried
out of a number of gas mixtures: $\text{WCl}_6 - \text{WCl}_5 - \text{Cl}_2$;
 $\text{WOCl}_4 - \text{WO}_2\text{Cl}_2 - \text{WCl}_6 - \text{Cl}_2$ and $\text{WO}_2\text{Cl}_2 - \text{WO}_3 - \text{WOCl}_4 - \text{WCl}_6 - \text{Cl}_2$.
For the system $\text{WOCl}_4 - \text{WCl}_6 - \text{WO}_2\text{Cl}_2$ the temperature
dependence of p and L is also shown by a diagram in figure 4.
There are 4 figures and 1 Soviet reference.

Membrane Zero Pressure Gauge for the Measurement of Vapor Pressure in a Broad Temperature Interval (Membrannyy nul'manometr dlya izmereniya davleniya parov v shirokom intervale temperatur)

PERIODICAL:

Zavodskaya Laboratoriya, 1959, Vol 25, Nr 6, pp 750-751 (USSR)

ABSTRACT:

Several years ago a production technique was worked out of membranes for zero pressure gauges without the shortcomings of the pressure gauges according to reference 2 (Ref 1). As the membrane chamber is also in the present case not quite small enough, a device with smaller dimensions and a flat membrane was constructed. The pressure gauge may be made of molybdenum- or pyrex glass as well as of quartz (figure 1, scheme of the pressure gauge). The glass membrane is made from a glass ball which is blown and then flattened (Fig 2). A rodlet is melted on to the surface the shift of which in connection with a motion of the membrane indicates a change in pressure on an opposed needle. The sensitivity of measurements depends on the quality of the membrane, the thickness of the rodlet and the deviation of the top of the

TITLE:

Method of Determining the Pressure of the Saturated Vapor
of Difficultly Volatile Substances

PERIODICAL: Zavodskaya laboratoriya, 1959, Vol 25, Nr 9, pp 1097-1099 (USSR)

ABSTRACT: A method was developed by which the sample is vaporized in an inert gas in a closed vessel, the inert gas acting as an elastic medium which transfers the vapor pressure to a pressure gauge outside the high-temperature range. From the scheme of the gauge (Fig 2) it may be seen that the substance to be investigated evaporates in a cylindrical quartz vessel which is housed in a furnace and is connected to a diaphragm zero-pressure gauge by means of a tube. The latter is contained in a thermostat and transmits the pressure to the pressure gauge which permits measurements with an accuracy of ± 0.5 torr. From the measurement results obtained on the apparatus described the pressure of the saturated vapor of KCl was computed, and a curve of the dependence of the vapor pressure on temperature was plotted (Fig 3). Comparison with the corresponding values in Stell's table shows good agreement of the data.
There are 3 figures.

TITLE: The Thermodynamic Properties of Chlorides and Oxychlorides
of Tungsten and Molybdenum

PERIODICAL: Zhurnal neorganicheskoy khimii, 1960, Vol. 5, No. 8,
pp. 1650-1654

TEXT: By applying various methods, the authors wanted to check the formation heats, formation entropies, and formation enthalpies in the case of Mo- and W chlorides, published in western papers (Refs. 1, 2). They investigated: WCl_6 , MoCl_5 , WOCl_4 , MoCl_4 , WO_2Cl_2 (obtained by a successive chlorination of WO_3 and MoO_3 by means of CCl_4); MoO_2Cl_2 (obtained by the reaction between MoO_2 and Cl_2); MoCl_3 , WCl_4 , WCl_5 (by the reduction of MoCl_5 and WCl_6 by means of H_2), and MoCl_2 , WCl_2 (obtained by disproport-

Card 1/3

tion of MoCl_3 , and WCl_4 , and MoOCl_4). Two calorimetric methods were applied:
1) Comparison of the heat of solution of the investigated substance to the
heat of solution of a substance whose heat of formation is known (Table 1).
2) Combustion in oxygen (Table 2). Furthermore, the vaporization, depoly-
merization, dissociation, and disproportionation processes taking place in
a state of equilibrium, were spectrophotometrically and tensimetrically
investigated (Tables 3, 4). The enthalpies of formation, and partly also
the standard entropies of formation were calculated from the experimental
data. In Tables 5 (Mo compounds) and 6 (W compounds) they are compared
with the data given in Ref. 2 which were adopted almost unchanged by the
US National Bureau of Standards (Ref. 9). The values determined by the
authors are 1.4 - 1.7 times as high. Therefore, the dependence of the
free energy of formation of temperature is different altogether. This is
graphically represented in Fig. 1 (comparison of determined ΔH° and ΔF°
for tungsten compounds, with the data of the National Bureau of Standards).
and Fig. 2 (comparison of the $\Delta H^\circ_{\text{form}}$ of Cr, Mo, and W chlorides, with
the data of the National Bureau of Standards). There are 2 figures,
6 tables, and 9 references: 6 Soviet, 2 US, and 1 Dutch.

TITLE: Thermographic method of measuring the pressure of saturated vapors of difficultly volatile compounds

PERIODICAL: Zhurnal neorganicheskoy khimii, v. 6, no. 8, 1961. '951-'952

TEXT: The authors used the "boiling point" method which has the advantages of the method by L. G. Berg (Ref. 2: IZV, Sektory fiz.-khim. analiza, 22, 140 (1953)). This method makes it possible to determine the moment when the vapor pressure of the substances equals the pressure outside the reaction vessel. In the present case, this moment was determined from the temperature drop of the substances, which occurred with their increasing evaporation near boiling point. The apparatus required is shown in Fig. 1. When experimenting with hygroscopic and easily oxidizable substances, the reaction vessel is connected to a vacuum apparatus and filled with pure and dry nitrogen. The current from the differential thermocouple is measured by a mirror galvanometer of 10^{-9} a/mm.m sensitivity. Gradual pressure drop was effected in the system at constant temperature, and the

TITLE: New method for the synthesis of low tungsten chlorides

PERIODICAL: Zhurnal neorganicheskoy khimii, v. 6, no. 4, 1961, 1464-1473

TEXT: The object for the present study was to elaborate a method permitting the production of larger quantities (kilograms) of low tungsten chlorides. Production by reduction of WCl_6 with hydrogen is not advantageous, and for larger quantities it also requires special apparatus because of the danger of explosion hazard. This study gives theoretical considerations and their experimental confirmation with regard to the reduction of WCl_6 with phosphorus. On the basis of the thermodynamic data (S. A. Shchukarev, G. I. Novikov et al., Referaty dokladov VIII Mendeleyevskogo s'ezza, (Abstracts of the reports from the 8th Mendeleyev Congress), n. 4, sektsiya fiz. khimii, M., 1958, p. 220), a good yield of the compounds WCl_2 and WCl_4

Card 1/4

New method for the synthesis...

B107/B101

is found to form from WCl_6 and white phosphorus at $200^{\circ}C$. Moreover, the equilibrium of the reaction $[WCl_4]_s + [PCl_3]_g = [WCl_4]_s + [POCl_3]_g$ at $200^{\circ}C$ lies almost entirely on the right-hand side, so that the final reduction product would be free of contaminating oxychloride (s = solid; g = gas). Phosphorus has also the advantage that it may be accurately dosed and the reaction conducted in the evacuated glass vessel. Red phosphorus was used for the experiments and the reaction temperature was therefore raised to $250-300^{\circ}C$. WCl_6 was prepared by reaction of tungsten with chlorine at $500-600^{\circ}C$. A glass apparatus (Fig.) was used for preparing low chlorides. WCl_6 and phosphorus were filled into vessel B. For the preparation of WC_5 , slightly more than the stoichiometrically required quantity of phosphorus was used, slightly less for that of WC_4 . The vessel is then evacuated and sealed at a. B is heated to $250-300^{\circ}C$, the volatile PCl_3 and $POCl_3$ are condensed in C. After the reaction, C is

Vapor hydrolysis of K halide ...

The examination was conducted by the static method with a thin layer technique. The enthalpy of formation of KCl , LaCl_3 , $2\text{KCl}\cdot\text{CaCl}_2$, $2\text{KCl}\cdot\text{MgCl}_2$, $3\text{KCl}\cdot\text{NaCl}_3$, $2\text{KCl}\cdot\text{FeCl}_3$, $2\text{KCl}\cdot\text{NiCl}_2$, and $3\text{KCl}\cdot\text{NdCl}_3$, was calculated from experimental data by the equation

$$\Delta S_{\text{formation}}^{\circ} = \frac{\Delta H_{\text{formation}}}{T} + 4.575 (\log K_p^{\circ} - \log K_p^{\circ}).$$

Pure chlorides of rare earths were produced by chlorination of the oxides with $\text{CCl}_4 + \text{Cl}_2$ at 600-700°C. They were distilled in a vacuum to remove hydrochloric traces. A neutral salts of rare earths were prepared by stoichiometric amounts of rare earth chlorides and a chloride at 700°C in evacuated quartz ampoules. The equilibrium of water vapor hydrolysis was maintained in a quartz apparatus with a liquid nitrogen stage. The temperature was measured with a platinum-rhodium thermocouple and kept constant with a 377-01 (LIV-01) thermoregulator accurate to 0.5°C. The atmospheric pressure in the apparatus was measured with a gauge accurate to 0.1 mm. The more rare earth chlorides are contained in the ionic salts, the greater is the vapor hydrolysis at the corresponding temperatures. The result is

ANALYSIS OF K-CHLORINE

3/254/86/ccc/101/101
P121, 1-2

An analysis of the K-chlorine binary system has been made. The results given in Table I were compared with published literature. The relative thermal stability of these compounds is based on the literature values and permits a ranking of the stability of the binary systems. The following compounds are listed in order of increasing thermal stability: $\text{KCl}\cdot\text{CaCl}_2$, $\text{KCl}\cdot\text{MgCl}_2$, and $\text{KCl}\cdot\text{MgO}$. The following references were used:

Apparatus for determining vapor pressure by the method of saturation
and its use in the determination of the vapor pressure of the substances, the
dissociation constants of which are known. For this purpose, the
apparatus consists of a glass vessel containing H_2O , NaCl , KCl ,
 MgCl_2 and CaCl_2 , and a "saturation-vapor pressure apparatus" method
was determined by an additional method of the apparatus. In 1951, G. V.
G. L. Novikov, N. N. Sivchenko, I. V. Kozin, A. I. Vasil'ev,
It is suitable for measuring the vapor pressure of liquid and solid
substances from 1 mm Hg to atmospheric pressure and above. Error
 15 ± 1 mm Hg. The moment at which the vapor pressure above the
substance becomes equal to the external pressure is established by the
drop in the temperature of the substance when evaporation is intensified
near boiling point. The temperature ranges were 1124-1210°C for LiCl .

1093-1224°C for CeCl_3 , 1041-1192°C for PrCl_3 , and 962-1194°C for NdCl_3 . The results are given in Fig. 3. Those for NdCl_3 are only approximate, as the initial Nd was contaminated by ~ 4% Pr. Table 6 gives the boiling points, evaporation enthalpies, and evaporation entropies derived from the results. The boiling points are lower than the corresponding published data (S. I. Harrison, J. Amer. Chem., 2, 601 (1952); V. V. Serebrennikov, Khimiya redkozemel'nykh elementov (Chemistry of Rare Earth Elements), Tomsk, 1959, p. 203; R. C. Vickery, Chemistry of the Lanthanons, London, 1953, p. 229). The entropies of fusion were calculated from the melting points of the chlorides studied, and from the heats of fusion given in the above references (Table 7). The evaporation and sublimation enthalpies calculated mainly from experimental data are considerably higher than the published figures (An. N. Nesmeyanov, L. A. Sazonov, Zh. neorgan. khimii, 4, 230, 231 (1959)). There are 3 figures and 7 tables.

AUTHOR: I. I. Lopatin et al., Russia

TITLE: Determination of vapor pressure above melts in the system LiCl-KCl-LnCl₃ (Ln = La, Ce, Pr, Nd, Eu, Gd, Tb, Dy, Er, Tm)

JOURNAL: Journal of Non-Crystalline Solids, v. 10, p. 111-115, 1970

TEXT: The total vapor pressure above melt of the systems LiCl-Ln₂O₃ (Ln = La, Ce, Pr, Nd, Eu, Gd, Tb, Dy, Er, Tm) was studied in the temperature range 90-110°C using an existing modification of the "boiling point method" (sensitivity 0.1 mm Hg). For determining vapor pressures of low-volatility substances (LiCl) the technique of V. I. Lopatin, S. I. Polyanskiy, Yu. N. Kozman, Khimil, 1971 (1971). In the resulting diagrams (log P_{total}; ln P_{total}; ln P_{total}/T, °K) the lines of the total saturation vapor pressure for melts of different compositions lie between those of the pure components KCl and LnCl₃. Their order agrees with the changes in concentration of the melts. There is non-monotonic variation in the rise of the vapor pressure line when passing from pure

Card 1/3

Pressure and composition of ...

815, 316

LnCl₃ salt - mixtures contain up to 20% LnCl₃. This may be due to the incorporation of the components in the melt at the temperature range. The systems studied deviate considerably from ideal mixtures, in a way which indicates considerable association in the salt melts. With the analytical methods described analysis of the borates is possible. The sum of the analytically determined elements was in good agreement with the results of direct weighing of the borates. Comparison of the vapor compositions with the corresponding compositions of melts showed that the vapor contained far more lanthanum than could be expected if only KCl and LnCl₃ are actually soluble without the formation of double salts or their evaporation on heating. Plots of vapor versus melt composition show that some form of the double salts between KCl and LnCl₃ must be volatile. The rare earth content of the vapor decreases with rising temperature, which may be due to dissociation of the volatile forms of the compounds in the melt. There are 9 figures and 10 tables.

TITLE: Saturated vapor pressures of liquid chlorides of certain lanthanons and over the systems MCl_3 , KCl , where
M La, Ce, Pr, Nd

PERIODICAL: Zhurnal obshchey khimii, v. 13, no. 1, 1933, p. 110-116

TEXT. The vapor pressures were measured by a variation of the familiar 'ew-point' method, over molten $LaCl_3$, $CeCl_3$, $PrCl_3$, and $NdCl_3$ at $1124-1220^\circ$, $1093-1224^\circ$, $1041-1192^\circ$ and $962-1194^\circ C$ respectively. Dependence of the pressure on temperature was of the usual form $\ln P = f(1000/T^\circ K)$ and ΔH_{evap} and ΔS_{evap} have been determined [Abstractor's note: ΔH and ΔS not defined but probably latent heat and entropy]. Boiling points of $LaCl_3$, $CeCl_3$, $PrCl_3$, and $NdCl_3$ were found to be 1570° , 1555° , 1554° and $1551^\circ C$, i.e. 10°

Card 1/2

200°C below values quoted in the literature. Vapor pressures were also measured over 9 binary chloride systems of form $(MCl_3)_x \cdot KCl^y$ between $\sim 100^\circ C$ and $\sim 600^\circ C$ and the sublimes (10^{-15} % of the original 0.45-0.50 g samples) were analyzed for Cl and M. It was found that the concentration of M in the vapors decreased at higher temperatures which is thought to be connected with the dissociation of volatile forms of the compounds. There are 2 tables and 8 references. 5 Soviet bloc and 3 non-Soviet-bloc. The references in the English-language publications read as follows: E. Harrison J. Appl. Chem., 2, 601, 1952, Vickery "Chemistry of the Lanthanons" [Abstractor's note: Essentially complete translation].

TITLE: Stability of lower rare-earth chlorides

SOURCE: Zhurnal neorganicheskoy khimii, v. 8, no. 7, 1567-1573

TOPIC TAGS: rare earth, rare-earth chloride, rare-earth enthalpy, rare-earth disproportionation, rare-earth reduction, Born-Haber cycle, Lanthanide chloride, NdCl sub 3, NdCl sub 2, NdCl

ABSTRACT: The thermochemical data required for the determination of the stability of lower rare-earth chlorides have been obtained. The heats of formation of NdCl₂ and NdCl₃ were determined calorimetrically to be -163.2 and -246.5 kcal/mol, respectively. From these heats of formation the enthalpy change in the disproportionation of NdCl₂ by the reaction:

was calculated to be -3.4 kcal, and ΔS° , 15 ± 1 EU. The temperature of non-variant equilibrium of the disproportionation was found to be -46°C, below which

Card 1/63

L 13049-63

NdCl_2 is thermodynamically unstable and can only exist in the frozen state. The heats of formation of lanthanide (Ln) dichlorides in the solid state were calculated by means of the Born-Haber cycle and are given in Table 1 of the Enclosure. The data in Table 1 suggest that the heat of sublimation is the main factor which determines the heats of formation of the lower rare-earth chlorides. On the basis of the data given in Table 2, for LnCl_2 disproportionation by the reaction:

the following qualitative conclusions concerning the stability of the rare-earth dichlorides were made: 1) In addition to the known SmCl_2 , EuCl_2 , and YbCl_2 , the stable dichlorides PmCl_2 and TmCl_2 can be obtained. 2) Among the less stable dichlorides, in addition to the known NdCl_2 and PrCl_2 , it is apparently possible to obtain in the solid state DyCl_2 and HoCl_2 , which are stable at elevated temperatures only, and ErCl_2 , which is apparently stable at room temperature. 3) Formation of LaCl_2 , CeCl_2 , GdCl_2 , and TbCl_2 cannot be expected in the solid state or in the melt. Calculation of the equilibrium constants for hydrogen reduction of LnCl_3 to LnCl_2 revealed the possibility of complete reduction of SmCl_3 , EuCl_3 , and YbCl_3 , but of only partial reduction in the case of Nd, Pm, Dy, Ho, Er, or Tm. Calculation of heats of formation of LnCl by means of the Born-Haber cycle

TITLE: On the pressure of saturated vapor in the $\text{LaCl}_3\text{-La}$, $\text{PrCl}_3\text{-Pr}$, and $\text{NdCl}_3\text{-Nd}$ systems

SOURCE: Zhurnal neorganicheskoy khimii, v. 8, no. 7, 1963, 1785-1786

TOPIC TAGS: rare earths, rare earth chlorides, lanthanum, praseodymium, neodymium, PrCl_3 , NdCl_3 , LaCl_3 , vapor pressure, solubility, boiling-point method, heat of reaction, Pr(II), Nd(II)

ABSTRACT: The vapor pressure of the $\text{PrCl}_3\text{-Pr}$, $\text{NdCl}_3\text{-Nd}$, and $\text{LaCl}_3\text{-La}$ systems and the solubility of the rare earths in the chlorides of these systems were determined in the 1180—1350°C range. The vapor-pressure samples weighing 0.1—0.2 g were measured by the "boiling-point" method in heavy-walled quartz ampoules lined with molybdenum to prevent reaction of the rare earths with quartz. Vapor-pressure diagrams plotted (see Enclosure), indicate that

Card 1/5

ACCESSION NR: AP3003486

dissolution of atomic La occurs and that ions of Pr(II) and Nd(II) form in the melt. In all three systems the trichloride was the only compound to vaporize. Instability of the dichlorides in the vapor phase is probably associated with their high heat of vaporization. The positive deviation from Raoult's law observed in the $\text{PrCl}_3\text{-Pr}$ system may be attributed to the presence of some atomic Pr. The experimental heat of vaporization in the single-phase region was close to that of the pure chlorides (LaCl_3 , PrCl_3 , and NdCl_3), indicating that the overall heat effect of processes occurring during the dissolution of the trichlorides in the melt was close to zero. The difference between the heat of vaporization of the pure trichlorides and that of NdCl_3 and PrCl_3 in the phase-separation region is governed by the heat of reaction of the disproportionation of the dichlorides. The latter was found to be 38 ± 10 kcal for NdCl_2 at an average temperature of 1250°C , and 24 ± 10 kcal for PrCl_2 at an average temperature of 1230°C . For thermodynamic calculations from the data obtained on the disproportionation of the dichlorides, more precise information concerning the nature of ions formed in the melt on dissolution of the metals, as well as experimental data on

SmCl₂. Compounds EuCl₂ and YbCl₂ are readily obtained by reduction of the trichlorides with metallic zinc. Scandium¹¹dichloride (ScCl₂) melted at 806°C with decomposition. In the ScCl₃-Sc system the intermediate compound 2ScCl₃·ScCl₂, which decomposes on melting, was obtained. The solubility of yttrium in YCl₃ was only 2 mol% at the eutectic temperature, 716°C. Vapor pressure measurements for the LaCl₃-La, PrCl₃-Pr, NdCl₃-Nd²⁺YCl₃-Y, and ScCl₃-Sc systems show that atomic dissolution of La and Y occurs and that divalent ions of Pr²⁺, Nd²⁺, and Sc²⁺ are formed in the melt. For the disproportionation of the dichloride to the trichloride and the metal, ΔH° was found to be 13 kcal/mole for NdCl₂ and 8 kcal/mole for PrCl₂; in both cases ΔS° was equal to 3 eu (at an average temperature of 1250°C). The standard enthalpy of formation was -163.2 kcal/mole for NdCl₂ and -246.5 kcal/mole for NdCl₃. For solid PrCl₂ and ScCl₂ the enthalpy of formation was approximately -163 and -145 kcal/mole, respectively.

TITLE: Fusibility diagrams of systems formed by samarium and ytterbium di- and trichlorides with potassium chloride

SOURCE: Zhurnal neorg. khim., v. 9, no. 2, 1964, 472-475

TOPIC TAGS: samarium dichloride, samarium trichloride, ytterbium dichloride, ytterbium trichloride, potassium chloride, binary chloride fusibility, fusibility diagram

ABSTRACT: This work resulted from the lack of data on the stabilizing action of alkali halides on the dihalides of rare earths. The formation of solid phase compounds was observed and complexes were traced in the liquid and gaseous phases of trichlorides. Since there also is no literary data on the effect of KCl on rare earth dichlorides, fusibility tests of Sm and Yb di- and trichlorides with KCl were made and fusibility diagrams plotted. It was found that the solid state compound $KCl \cdot 2SmCl_2$ decomposes during melting, while $KCl \cdot YbCl_2$ melts without decomposition. There is a similarity of

Card 1/2

ACCESSION NR: AP4012450

these fusibility diagrams with those of $\text{SrCl}_2\text{-KCl}$ and $\text{CaCl}_2\text{-KCl}$ due to the similarity of ionic radii of $\text{Sr}^{2+}\text{-Sm}^{2+}$ and $\text{Ca}^{2+}\text{-Yb}^{2+}$ (1.27 and 1.06 Å). The $\text{SmCl}_3\text{-KCl}$ system showed, in addition to the $3\text{KCl}\cdot\text{SmCl}_3$ and $2\text{KCl}\cdot\text{SmCl}_3$ (already known), a new compound $\text{KCl}\cdot 2\text{SmCl}_3$, while the $\text{YbCl}_3\text{-KCl}$ system forms only $3\text{KCl}\cdot\text{YbCl}_3$. Complex ions were observed in the liquid state. It was also found that a marked influence of KCl on the relative stability of rare earth di- and trichlorides can only be expected for neodymium dichloride. Orig. art. has: 2 Figures.

TITLE: Dissociation pressures of samarium, europium and ytterbium trichlorides

SOURCE: Zhurnal neorganicheskoy khimii, v. 9, no. 4, 1964, 773-777

TOPIC TAGS: samarium trichloride, europium trichloride, ytterbium trichloride, dissociation pressure, thermodynamic characteristic, static method, zero manometer, dissociation constant, heat of formation, entropy of formation, hydrogen reduction, samarium dichloride, europium dichloride, ytterbium dichloride, solid trichloride, liquid trichloride, solid dichloride, liquid dichloride

ABSTRACT: The dissociation pressures of molten SmCl_3 , EuCl_3 , YbCl_3 ($\text{LnCl}_3\text{liq.} \rightleftharpoons \text{LnCl}_2\text{liq.} + 1/2\text{Cl}_2$) were measured, and from these the thermodynamic characteristics for these rare earth di- and trichlorides were calculated. The chlorine pressures at temperatures up to 1000°C were measured by the static method with a quartz-membrane zero manometer (G. L. Novikov, A. V. Suvorov).

Card 1/3

ACCESSION NR: AP4029180

Zavodsk. laboratoriya, 25, 750 (1959)). The dissociation constants for SmCl_3 and YbCl_3 were calculated according to the equation: $K = \frac{2V}{RT} \cdot \frac{P_{\text{Cl}_2}}{P_{\text{Cl}_3}}$, and of EuCl_3 , in which chlorine formation is much greater, by the equation: $K = \frac{2V}{RT_{\text{Eu}}} \cdot \frac{P_{\text{Cl}_2}}{P_{\text{Cl}_3}}$.

From these data the standard heat and entropy of formation of the Sm, Eu and Yb di- and trichlorides were calculated. The data agree with literature values. Calculations were also carried out for the equilibrium in the dissociation of the solid trichlorides according to the equation: $\text{LnCl}_3\text{solid} \rightleftharpoons \text{LnCl}_2\text{solid} + 1/2\text{Cl}_2$ and for the reduction of the trichlorides with hydrogen: $\text{LnCl}_3 + 1/2\text{H}_2 \rightleftharpoons \text{LnCl}_2 + \text{HCl}$. The equilibrium chlorine pressures over the molten trichlorides at 1100-1400 °C were determined:

$$\text{SmCl}_3\text{molten} \lg P_{\text{Cl}_2, \text{H}_2} = 41,82 - \frac{17450}{T} - 9,061 \lg T$$

$$\text{EuCl}_3\text{molten} \lg P_{\text{Cl}_2, \text{H}_2} = 41,79 - \frac{17300}{T} - 9,061 \lg T$$

$$\text{YbCl}_3\text{molten} \lg P_{\text{Cl}_2, \text{H}_2} = 41,65 - \frac{19300}{T} - 9,061 \lg T$$

TITLE: Vapor pressure and vapor composition in the potassium chloride-samarium, ytterbium, calcium and strontium dichloride systems

SOURCE: Zhurnal neorganicheskoy khimii, v. 9, no. 4, 1964, 1017-1019

TOPIC TAGS: potassium chloride containing system, samarium dichloride containing system, ytterbium dichloride containing system, calcium dichloride containing system, strontium dichloride containing system, vapor pressure, vapor composition, KCl-SmCl₂ sub 2 system, KCl-YbCl₂ sub 2 system, KCl-CaCl₂ sub 2 system, KCl-SrCl₂ sub 2 system

ABSTRACT: The saturated vapor pressures in the KCl-SmCl₂, KCl-YbCl₂, KCl-CaCl₂ and KCl-SrCl₂ systems, and the gross vapor composition of the latter two systems were determined. The saturated vapor pressures were obtained by the "boiling point" method at 1050 and 1150 C above melts containing 25, 50 and 75 mol.% KCl (figs. a, b). The data show the systems deviate from Raoult's law only slightly, and that the KCl-CaCl₂ and KCl-YbCl₂, and the KCl-SrCl₂ and KCl-SmCl₂ systems are

Card 1/3

ACCESSION NR: AP4029196

similar. The gross composition of the vapor (the potassium and the alkaline earth content) at 1050 and 1150 C was determined by flame photometry. The data show the alkaline earth dichloride potassium chloride ratio is independent of temperature. This ratio (MCl_2/KCl) does decrease with increase in initial KCl content in the melt, and decreases in going from Ca to Sr. Orig. art. has: 3 tables, 1 figure.

TITLE: Halides of the rare earth elements at a lower oxidation state

SOURCE: Uspokhi khimii, v. 33, no. 6, 1964, 732-747

TOPIC TAGS: literature review, survey, rare earth element, rare earth metal compound, divalent rare earth compound, rare earth dihalide, rare earth trihalide, metallocothermal reduction, hydrogenation, vacuum dissociation, divalent rare earth oxychloride, divalent rare earth oxide, divalent rare earth chalcogenide, divalent rare earth senide, divalent rare earth telluride, divalent rare earth sulfide, physical property, physical chemical property, calorimetry, heat of formation, enthalpy of formation, phase diagram, saturated vapor pressure, electric conductivity, density, dissociation, free energy, entropy, rare earth dichloride, rare earth difluoride

ABSTRACT: This literature review is directed to the rare earth elements in the divalent state, particularly to their halogen compounds which must occur as intermediates in the production of the rare earth metals during the electrolysis or

Card

1/3

ACCESSION NR: AP4040531

metallothermal reduction of the trihalides. Knowledge of the properties of the halides would help establish optimum process conditions and reduce electrolytic losses. It is thought that the differences in the stabilities in the lower degree of oxidation might be utilized in the separation of the elements. This summary includes a short outline of the chemistry of the compounds of the rare earth elements in the lower oxidation state, the properties and the synthesis of the rare earth dihalides (hydrogenation, vacuum distillation, metallocothermal reduction including reaction with the corresponding rare earth metal, of the rare earth trihalides) and of the oxychlorides, oxides, and chalcogenides (sulfides, selenides, tellurides). Particular attention is given to the physical and physical-chemical studies on the rare earth dichlorides. Also discussed are the calorimetry of the dichlorides and determinations of their heat and enthalpy of formation, phase diagrams, saturated vapor pressures, electric conductivities and densities of the rare earth trichloride-rare earth metal systems, the dissociation of Sm, Eu, and Yb trichlorides: $\text{LnCl}_3\text{(l)} \rightleftharpoons \text{LnCl}_2\text{(l)} + \frac{1}{2}\text{Cl}_2\text{(gas)}$ and their free energy, heat of formation and entropy. Summarizing the possibility of the existence of rare earth dihalides, the authors conclude that stable Pr Cl_2 and Tm Cl_2 should be obtainable in addition to the known Nd, Sm, Er, Yb and Sc dichlorides, and the less stable Ho Cl_2 and Er Cl_2 should also be obtainable in addition to Pr Cl_2 , but La, Ce,

TITLE: Complex formation in the vapor phase of the system erbium trichloride - potassium chloride

SOURCE: Zhurnal neorganicheskoy khimii, v. 10, no. 7, 1965, 1668-1674

TOPIC TAGS: erbium compound, erbium chloride, potassium chloride, potassium compound, complex formation, rare earth

ABSTRACT: Data were obtained on the volatility and stability in the vapor phase of the complex $KErCl_4$ in the KCl - $ErCl_3$ system at 800-1200°C. From the experimental data on the saturated vapor pressure as a function of temperature, the thermodynamic characteristics of the equilibrium

and of the hypothetical sublimation process

Card 1/2

L 61033-65

ACCESSION NR: AP5018250

were calculated. The existence of the compound $KErCl_4$ in the vapor phase is indicated by the fact that a maximum appears on the curve representing the partial pressures of $ErCl_3$ and KCl versus the composition of the melt (the other pure substances present in the vapor are $ErCl_3$, KCl , and K_2Cl_2). On the basis of certain data obtained and also literature data, it is concluded that the formation of stable complex compounds takes place in $KCl - LnCl_3$ systems (which include the entire rare earth family, Ln being a lanthanide). The compound $KLnCl_4$, which does not exist in the crystalline state, vaporizes from the melts, and its content in the vapor increases in the $La - Lu$ series. Orig. art. has: 5 figures, 4 tables, and 19 formulas.

TITLE: Preparation of anhydrous chlorides of the rare earth elements

SOURCE: Zhurnal prikladnoy khimii, v. 38, no. 5, 1965, 1160-1161

TOPIC TAGS: anhydrous chloride, chloride, rare earth element, carbon tetrachlorite

ABSTRACT: High purity anhydrous lanthanum and erbium chlorides (LaCl_3 , ErCl_3) were prepared from $\text{La}_2(\text{C}_2\text{O}_4)_3$ and $\text{Er}_2(\text{C}_2\text{O}_4)_3 \cdot 4.5 \text{H}_2\text{O}$, respectively. In each case a 3 to 4 gram sample of oxalate was placed in a quartz vessel and a mixture of CCl_4 and chlorine was blown over the sample for 30-40 minutes at 200°C in order to remove air and moisture. Then the temperature was raised to 400° to 450°C and the oxalate sample was subjected to the $\text{CCl}_4\text{-Cl}_2$ mixtures (chlorine saturated with carbon tetrachloride at room temp.) for 2.5 to 3 hours. The flow rate of the $\text{CCl}_4\text{-Cl}_2$ mixture was about 3 to 4 l/hr. Finally the temperature was raised for a short time to 600°C . The resulting product was found analytically to be close to 100% LaCl_3 or ErCl_3 . Spectral analysis showed the total impurity (Fe, Al, Ca, Mg,

Card 1/2

L 54959-65

ACCESSION NR: AP5014164

Ti, Cr, and Mn) to be less than 0.1%. It is concluded that this method may apply also to other rare earth elements since all the oxalates of rare elements decompose at a temperature close to 400°C. Orig. art. has: 1 table, 1 figure, and 2 formulas.

TITLE: Vapor pressure and composition in the KCl-ThCl₄ system

SOURCE: Zhurnal neorganicheskoy khimii, v. 11, no. 3, 1966, 498-503

TOPIC TAGS: vapor pressure, potassium chloride, thorium compound, potassium compound, strontium compound, lanthanum compound

ABSTRACT: In this work, which constitutes the first attempt to study compounds of ML-Cl-ThCl₄ systems in vapor form, the total vapor pressure in the KCl-ThCl₄ system was measured by the boiling point method. The vapor pressure data obtained by analyzing the condensates over the melts can be explained only by assuming that a complex compound to which the composition KThCl₅ was ascribed by analogy with NaZrF₅ passes into the vapor state (the other substances present in the vapor are KCl, K₂Cl₂, and ThCl₄). On the basis of the experimental data, the equilibrium constants were calculated for the dissociation of this complex:
