

variations of the catalase curve of blood after introduction of pilocarpine on an acid or alkaline diet. S. A. Povorinina. Russ. J. Physiol. 18, 189-92 (1930).—The curves representing the catalase content of the blood at various times after subcutaneous injection of pilocarpine are of a uniform type for children receiving an alk. but not an acidic diet; where a mixed diet is taken, the curves are of a mixed type. The catalase-time curves for children on an alk. diet not receiving pilocarpine are not of a uniform type. The catalase curves vary irregularly for the same individual according to the day and hour at which the blood is taken. No parallelism is found between blood catalase and hemoglobin contents.

TITLE : Effect of the addition of the plant extract on the
growth of fungi.

CRIC. PUBL: USSR, Ministry of Agriculture, Moscow, 1959,
No. 36

ABSTRACT : The author studied the effect of the addition of the plant extract on the growth of fungi. The results show that the addition of the plant extract to the culture medium inhibits the growth of fungi. The inhibition is more pronounced at higher concentrations of the plant extract. The author suggests that the plant extract may contain substances that inhibit the growth of fungi. The author also suggests that the plant extract may contain substances that stimulate the growth of fungi. The author concludes that the plant extract has a stimulatory effect on the growth of fungi.

TITLE: On the speed of cooling of magnico alloys

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya metallurgiya, no.1, 1963, 120-124

TEXT: Cast specimens 15 x 15 x 35 mm of AHKO 4 (Anko 4) (13.8% Ni, 8.4% Al, 23.5% Co, 3.11% Cu, rest Fe) were used to study the relationship between the magnetic properties and the structure for different rates of cooling and different temperatures. The residual induction was measured ballistically, the coercive force was determined by the Steblein method and the microstructure was studied at magnifications of 70 to 1440X. The dislocation densities were studied by the X-ray diffraction method of Williamson and Smallman. Two separate temperature ranges were investigated, 1280 to 800°C and 800 to 400°C, as above 800°C this alloy is single-phase at the cooling rate employed but between 800 and 400°C a two-phase structure $\beta_2 \rightarrow \beta + \beta_2$ is formed. In the experiments, the rate of cooling was varied in one temperature range, while kept constant in the

Card 1/4 ,

S/148/63/000/001/013/019

E073/E451

On the speed of cooling ...

other. A magnetic field of 1500 Ge was applied during cooling below 800°C; the maximum effect was experienced at 800 to 780°C. Whilst between 800 and 400°C the coercive force drops sharply with increasing cooling rate, the residual induction remains unchanged. At a cooling speed of 15 to 20 deg/min, the coercive force increases to its maximum value. Varying the cooling rates above 800°C, and maintaining a constant cooling rate (15 to 20 deg/min) below 800°C (the optimum from the point of view of the coercive force), bring about hardly any change in the coercive force but lead to a drop in the residual induction to 1000 gauss in the two limiting cases (very slow and very fast cooling rates). The highest residual induction is obtained with a cooling rate of about 200 deg/min between 1280 and 800°C and the maximum coercive force is obtained for a cooling rate of 15 to 20 deg/min below 800°C. Thermomagnetic treatment permits both these values to be increased, so achieving the highest possible magnetic energy $(BH)_{max}$. The basic magnetic characteristics achieved by ordinary and thermomagnetic treatment are determined by the state of the alloy in the two temperature ranges, above and below 800°C.

Card 2/4

S/148/63/000/001/013/019

E073/E451

Or. the speed of cooling ...

The cooling rate which gives the maximum residual induction (200 deg/min) reduces appreciably the coercive force if applied below 800°C, whilst the cooling rate corresponding to the maximum coercive force (15 to 20 deg/min) if applied in the temperature range 1280 to 800°C will lead to a sharp drop in the residual induction. Therefore, use of some average critical speed for the entire temperature range cannot be justified. The dislocation density results, which are in full agreement with the microstructure, show that the dislocation density is highest at high cooling rates and lowest at the intermediate cooling rate which gives the optimum residual induction. The optimum cooling rate for obtaining a maximum residual induction is the one which does not cause an excessively high density of dislocations and does not lead to decomposition along the grain boundaries. Since slow cooling leads to a more perfect alloy, it can be anticipated that alloying additions which increase the resistance of the high temperature solid solution to decomposition (for instance small amounts of titanium) will reduce the optimum cooling rate during heat treatment. It will then be possible to achieve a single critical rate throughout the entire cooling range. Its

Card 3/4

On the speed of cooling ...

S/148/63/000/001/013/019
E073/E451

value will be low, thus permitting heat treatment of magnets of varying cross-section using a single set of conditions. Alni alloys are usually subjected to rapid cooling from 1150 to 1200°C in boiling water, or to normalizing, to obtain maximum coercive force. However, the residual induction is low and the critical rate governs only the extent of low temperature decomposition $\beta_2 \rightarrow \beta + \beta_2$. It is possible that slower cooling to the temperature at which this decomposition begins would lead to an increase in the residual induction. There are 3 figures.

Functional states of the brain cortex resulting from the administration of phenamine and sodium amytaffine, their influence on the carbohydrate metabolism. Yu. A. Povorinskiy (V. M. Bekhterev Psychoneurological Inst., Leningrad). Zhur. Neuro-patol. i Psichiatrii im. Korakova 55, 8-16 (1955).—Under study were patients suffering of psychomotor agitation and of a state of depression-asthenia following the administration of phenamine (I) and Na amytaffine (II). Observations were also made on 3 normal controls and 3 exptl. dogs. Blood sugar depts. were made first on an empty stomach and at 30 min. intervals for 2.5 hrs. after the ingestion of 50 g. of glucose (sugar tolerance test). A few days later starvation blood sugar depts. were made again, 0.5 g. of II administered and 1 hr. later 50 g. of glucose ingested. Following another few days the procedure was repeated using 0.015 g. of I. I or II alone did not affect the blood sugar level during the first 2.5-3.0 hrs. After the administration of 50 g. of glucose to neuro-patients in a state of heightened agitation, the av. increase in the blood sugar was 43.6% and in patients in a state of depression-asthenia the av. increase was 64%. In 13 of the 17 patients in the state of depression-asthenia the rise in the blood sugar became manifest within 30 min. and in 10 of the 16 patients with symptoms of psychomotor agitation in 1 hr. after the glucose administration, but returned to the original level in 2 hrs. In 0.5-g. doses II caused all patients to fall into a 2-8 hrs. sleep. In 0.015 g. doses I brought about a state of increased agitation in the psychomotor patients and states of somnolence in 10 of the 17 depression-asthenia patients. The administration of glucose in the presence of I or II produced blood-sugar curves differing in a characteristic way from the blood-sugar curves produced by glucose alone.

Title : On the question of interaction between the first and second signal systems during the somnambulistic phase of hypnosis. Report II.

Periodical : Zhur. vys. nerv. deyat., 5, 11-18, Jan/Feb 1955

Abstract : The aim of this report is to clarify some peculiarities of bioelectrical activity of the brain (in healthy adults) during the somnambulistic phase of hypnosis in response to action of positive and inhibitive direct sound, light, and verbal stimuli. A limited focus of intensive excitation becomes formed in the second signal system during the somnambulistic phase of hypnosis. This arises as result of the simultaneous action of verbal and direct stimuli which are opposite in significance (one positive and one negative). These symptoms are connected, apparently, with the inductive inhibition of temporary connections in the first signal system. Five Soviet and six non-Soviet references. 11 diagrams.

TITLE: Along Pavlov's path

PERIODICAL: Priroda, no. 5, 1962, 25-33

TEXT: This very general article reviews present research into the higher nervous activity of man and animals. Specific breakthroughs or data collected during previous Soviet manned space flights are not mentioned. It is concluded that many problems of the higher nervous activity are still unsolved, above all the intimate nature of cortical excitation and inhibition, the mechanism and localization of the switching of temporary connections in the brain, the cortical-subcortical interrelations, and the regularities of the evolution of the higher nervous activity. A new approach is required for studying physiological processes on which the higher nervous activity and abstract thinking are based. Future manned space flights will help in studying factors affecting the state of the higher nervous activity

TITLE: Equipment for studying the Zeeman effect in a gas laser

SOURCE: Pribory i tekhnika eksperimenta, no. 4, 1966, 161-164

TOPIC TAGS: Zeeman effect, gas laser

ABSTRACT: The design of a special internal-mirror He - Ne laser and its application to studying the Zeeman effect are described. Two spherical mirrors 1 and 2 having radii of curvature of 120 and 129.6 cm, respectively, form the laser resonator (see figure).

Mirror 1 consisting of 17 sprayed layers of ZnS alternating with MgF₂ has a transmissivity of 0.4%; mirror 2 has 11 layers and a transmissivity of 1.2%. Quartz tube 3 stabilizes mirror 1 mechanically and prevents its angular displacement upon heating of internal tube 5 by the discharge. Mirror 2 can be adjusted; sylphon 7 serves as an anode. All

Card 1/2

dimensions are given in the article. The above laser was placed in a magnetic field (up to 500 oe) produced by a solenoid, and its radiation was observed by a Nicol-prism-photomultiplier-oscilloscope system. With a longitudinal magnetic field and at a wavelength of 6328 Å, the oscilloscope showed a sine wave whose frequency was equal to the difference of frequencies of the doublet line that represented the laser radiation. Seven oscillosograms are shown. Orig. art. has: 4 figures. [03]

TITLE: The Zeeman effect in an Ne-He laser

SOURCE: Optika i spektroskopiya, v. 21, no. 6, 1966, 754-758

TOPIC TAGS: laser, gas laser, ~~Ne-He laser~~, ~~Zeeman effect~~, ~~laser~~ Zeeman effect

ABSTRACT: The findings of several Western authors (Bell and Bloom, Appl. Opt., 3, 1964, 431; Fork and Patel, Proc. IEEE, 52, no. 2, 1964; Gordon and White, ibid.) concerning the Zeeman effect in gas lasers were experimentally confirmed on an Ne-He laser with inner spherical mirrors (radii of 120 and 129.6 cm and transmission coefficients of 0.4 and 1.2%, respectively). The length of the resonator was 111.8 cm. The corresponding difference between the resonance frequencies working on the $TEM_{0,0,q}$ wave, was 134.4 Mc. The dependence of the frequency difference of the doublet of the emission beam on the intensity of the longitudinal magnetic field was experimentally investigated. The oscillosograms showed, as expected, a widening between the beat frequencies (33 kc at 35 oe, 99 kc at 105 oe, 165 kc at 175 oe). Also, amplitude modulation was observed on the multiples of the above differential frequencies. The spectrum in the

Card 1/2

UDC: 539.184.28+621.375.9:535

ACC NR: AP7002423

presence of a magnetic field displays the usual picture of one central and two side peaks, the latter resulting from the superposition of waves with different polarizations. A periodic decrease of the beat amplitudes, observed when magnetic field strength was changed, was explained, in agreement with the theory, by a periodic coincidence of the Zeeman components with the resonant frequencies of the laser.
