Translation from: Referativnyy zhurnal, Geologiya, 1957, Nr 5,  
p 20 (USSR)

AUTHOR: Semikhatova, S. V.

TITLE: Choristites of the Group Choristites mosquensis Fischer  
From the Middle Carboniferous of the Don-Medveditsa  
Uplifts and Their Stratigraphic Significance (Khoristity  
gruppy Choristites mosquensis Fischer v srednem karbone  
Dono-Medveditskikh podnyatiy i ikh stratigraficheskoye  
znacheniiye)

PERIODICAL: Tr. Vses. n.-i. geol.-razved. neft. in-ta, 1956, Nr 7,  
pp 73-116.

ABSTRACT: The author describes and illustrates eight species of  
brachiopods (four of these are identified approximately)  
from the upper part of the Moscovian series (Podol'skiy  
and Myachkovo horizons) from the Archedin'sko-Don'skoy region  
and the village of Zhirnoye on the Medveditsa River. More  
Card 1/3 details are furnished for Choristites mosquensis, the

15-57-5-5854

Choristites of the Group Choristites mosquensis (Cont.)

varieties of which have 1) a sinus that broadens in the anterior part of the ventral valve, 2) a strongly beaked ventral valve, and 3) rather thin ridges. The specific content and course of development of Choristites mosquensis in this region are the same as in the central part of the Russian platform. The group thrived in Podol'skoye time and died out at the end of the Myachkovo interval. But at the time that this group was the principal form in the Moscow basin, other varieties were also present, whereas in the Archedinsko-Donskoy region the group was not only dominant, other forms (Choristites priscus and C. trautscholdi) were extremely rare. The general character of the sediments, their thickness, and also the fossil content show that the Carboniferous deposits of this region are of the platform type and should not be considered transitional to the Donets type. However, the path of migration for the fauna through the Middle Carboniferous connection between the Donets sea and the seas of the central and eastern regions of the Russian platform passed through the southern part of the Don-Medveditsa uplift zone. There is reason to believe that at the end of Moscovian time there was a small general uplift of the Voronezh massif, but this view needs support

TITLE: Some Problems in the Stratigraphy of the Lower Part of the Lower-Carboniferous System (Nekotoryye voprosy stratigrafii nizhney chasti nizhnego karbona)

PERIODICAL: Byulleten' Moskovskogo Obshchestva Ispytateley Prirody. Otdel Geologicheskiiy, 1957, # 6, pp 133-135 (USSR)

ABSTRACT: In April 1957, the All-Union Scientific Research Geological-Survey Petroleum Institute (VNIGNI) called a meeting dedicated to the stratigraphic problems of the lower part of the Lower-Carboniferous system.

The author cites the stratigraphic scheme accepted by the meeting and proposes some correlations between the subdivision of the European USSR of this scheme with the corresponding formations in Western Europe, basing his suggestions on the comparison of paleontological data. X

AVAILABLE: Library of Congress

The Upper-Kizelov Strata Near Buzuluk, -Chkalov Province. 20-4.47/61  
less silicified, little loam material. Similar limestones, predominantly organogen-detritus containing, with 45-60% organic relics. Among them foraminiferae, ostracodae, Crinoideae and ostracode splinters as well as pieces of tubular algae. In the upper part secondary dolomites occur with numerous single corals and bits of Crinoideae; 3rd packet, 21 m thick, consists of grey limestone of all shades, mostly recrystallized; numerous parts of fine-grained carbonate (?algae) and lenses of black flint. In the limestone a rather abundant fauna, however with few species, as above, is represented. Among the foraminiferae those with few windings as well such with a high number of windings are predominant. 4th packet, 24.74 m thick, consists of limestone, at the bottom with few intermediate layers of secondary dolomites, and thin layers of dark-grey siderites and black flint. Lime is grey, predominantly containing organogen-detritus, consisting of algae-Crinoideae, unevenly dolomitized in layers silicified. Dolomite is light- and dark-grey to almost black, highly recrystallized, calcareous at the bottom, pyritized, solid, on the top with rare incorporations of bluish-grey anhydride. The organic relics, here only appear, sporadically give evidence of the secondary nature of the dolomite. Fauna of foraminiferae has become very poor with the same arrangement of groups as in the two following packets. Corals indeterminate owing to bad conservation. In the overlying layer of this packet the modification of the combination of the foraminiferae and brachypoda. Ostracodes are present in several intervals. 5th packet, 24 m thick; separates according to the relief of

PERIODICAL  
ABSTRACT

These strata were here disclosed for the first time. They form an almost 200 m thick mass which consists mainly of gritstones and in the upper 48 m of terrigene rocks. Sea fauna is abundantly represented. The region is situated at the northern borde of the Caspian depression. As lower limit of the mentioned strata the authresses take the bottom of the Rakov-mass of V.M.Pozner. The Upper Kizelov-strata are deposited near Buzuluk in a depth of 2870 m. The upper boundary is taken in a depth of 2686 m, at a depth where the Kizelov-fauna is relieved by spores of the carboniferous horizon. Its thickness is 184 m. In both boundaries there is a stratigraphical incoincidence. At the Buzuluk cross-section these strata are separated into 6 pakets. 1st packet, 28 m thick, with high silification, terrigene sediments present, fauna poor. Rock is represented by dark-gray limestones, partially recrystallized, loamy-dolomitic at the bottom, siliceous-loamy higher up, in layers pyritized. Lenticularly black flint occurs. In the lower part-badly preserved brachypoda, sometimes silicified Crinoidea segments. Everywhere gravel spicules from fungi, rare ostracodae and, Archispaeren. 2nd packet, 38 m thick, is

Card 1/4

The Upper-Kizelov Strata Near Buzuluk, Chkalov province. 20-4.47/61  
its fauna. Lithologically not very different to the 4th packet. Limestone highly recrystallized. Fine- and small-grained calcite and less lump-shaped micro-grained carbonate serve as cement. Among the brachypoda the *Chonetes dalmanianus*, which is characteristic for the 3rd and 4th packet, here only appears sporadically. The most numerous are *Megachonetes zimmermanni* and *Pustula cf. pixidiformis*. At the bottom Spirifer-species and in an intermediate layer *Cacrinella aff.* and *ata* as well as frequent orthothetines-relics were found. In different depths corals (5 species) and ostracodes (5 species) are numerous. The 6th (terrigene) packet, 47.84 m thick, is composed of alternating marls, argillites, dolomites, and lime-loams, loamy limestones as well as dolomites and in the top contains intermediate layers of flints and siderites. In the cross-section argillites are predominant. In some argillites intermediate layers there are relics of corals, brachypodouses, pelecypodae and Crinoidae in high number. Moreover single ostracodes, fish relics, spores and pieces of vegetable tissues. In limestones there is a similar fauna, moreover pyritized plant relics, pieces of moss animals, trilobates, tubular algae and single badly preserved foraminifera capsules. According to the foraminifera and brachypoda the packets I.-V. could be compared with the mass of Rakow and possibly with the lower Malinov-masses of V.M. Pozner. L.F. Rostovtseva compares according to the foraminiferae the packets II.-IV. with the IV.-V.-masses of the Pilyugin cross-section and the packets III. and IV. with the Gubakha-

Card 3/4

The Upper-Kizelov Strata near Buzuluk, Chkalov province. 20-4-47/51  
packet. The brachypoda-complex of the VI. packet has no analogy in the  
kizelov faunae so far known. According to the foraminiferae the packet  
VI. ought to be classified to the kizelov horizon. V.A. Chizhova classifies  
the packets III.-VI. according to the ostracodes into the upper  
part of the Kizelov horizon. The brachypoda found in the Buzuluk cross-  
section: *Chonetes dalmanianus*, *Pustula cf. pixidiformis*, *Spirifer konin-*  
*cki*, *Sp. Aff. attenuatus* offer the possibility to classify the here des-  
cribed sediments into the *productus sublaevis*-zone. At the same time  
the entire above mentioned fauna of brachypoda confirms the necessity  
of classifying this zone among the *Wiesa* and not among the *Turna* as  
in the *Donez*-basin on the east slope of the Ural and in Western  
Europe.

TITLE

The Moscow stage of Middle Carboniferous in the Melekess Depression.  
(Moskovskiy yaruz Srednego karbona v Melekesskoy vpadine -Russian)

PERIODICAL

Doklady Akademii Nauk SSSR, 1957, Vol 113, Nr 5, pp 1119-1122 (U.S.S.R.)  
Received 7/1957

Received 8/1957

ABSTRACT

The deposits of the Moscow stage near the city of Melekess (in the territory of Kuybyshev-Samara) were laid open in a depth of 1167-785 m. The deposits of the Verey horizon (44 m) are concordantly stratified on the rocks of the upper part of the Bashkir stage. This horizon is subdivided into 3 lithological stratified packets. The lowest (8 m) consists of limestone with a sparse admixture of clay and intermediate strata of aleurites and dolomites. In limestone there is a lot of organogenic detritus of foraminifera, crinoids, brachiopods, and algae. The middle packet (30 m) is a varying stratification of clays, marls, aleurites, limestone, and rare dolomites. Clays are predominant, with 7-27% aleurite admixture, with calcareous intermediate strata which contain fragments of crinoids, brachiopods, as well as remains of plant tissue and lentiform intermediate strata of crushed brachiopod shells. The Kashir horizon consists of 2 stratified packets. The lower one (22 m) consists of limestone with inferior dolomites. The top packet (68 m) consists of limestone with thin clayey intermediate strata, its structure, however, is on the whole similar to that on the lower packet. The Podol horizon is at the top faintly characterized by fauna and its boundary is traced according to electric corotage. Compared to the Kashir horizon the dolomites are here more developed than the limestone. Among limestone, alga-

Card 1/3

The Moscow Stage of Middle Carboniferous in the Melekess 20-5-48/67 Depression.

limestones are characteristic. 3 stratified packets: 42, 49, and 36 m. In the lower organogenic -detrital clayey limestone with thin dolomite-intermediate strata and lentils of green clay dominate. Among the remains of organisms there are up to 20% bryozoa-flakes, elsewhere up to 15% siphonic-algae. In the second packet dolomites with clayey intermediate strata and rare prints of brachiopods predominate, inclusions of gypsum, anhydrite, and flint are found. The top packet is chiefly built of organogenic-detrital limestone with dolomite-intermediate strata in the middle part. The Myachkov horizon consists of limestone with dolomite-and clayey intermediate strata as in the Podol horizon. There are three packets: 6, 5, 25, and 88 m. Also here anhydrite, gypsum, and flint are to be found. The first packet consists of organo-detrital limestone with clayey intermediate strata, frequently such of shell-rock are up to 1, 5-3 cm thick. The second packet consists of dolomites with intermediate strata of organogenic-splintery and sometimes oolitic limestone. Foraminifera and brachiopods were determined. The third packet consists of varying stratifications of limestone, dolomite, and thin clayey strata of similar character as on the top. The total thickness of the deposits of the Moscow stage amounts in Melekess to 383 m and thus surpasses those of the right bank of the Volga to some extent. According to the rock-types of the single horizons and the total composition of the fauna the deposits of this stage in Melekess are equal to the deposits of the same age in the Tataric vault and in the central parts of the Moscow synclisis although local peculiarities are to be noticed.

TITLE:

Deposits of the Bashkirskiy Stage in Melekess (Otlozheniya bashkirskogo yarusa v Melekesse)

PERIODICAL:

Doklady AN SSSR, 1958, Vol. 118, Nr 2, pp. 381 - 383 (USSR)

ABSTRACT:

These sediments are deposited with a stratigraphic discordance on the rocks of the Protvinskiy horizon. The gap in the sedimentation manifests itself here in the development of lime-conglomerates and in a high secondary change of the rocks in the upper part of this horizon. The Bashkirskiy stage is 45 m thick and lithologically subdivided in 2 horizons of local importance. The exact identification of the latter may be carried out because of certain local differences of the foraminifera fauna. The lower horizon (probably analogous to the Molotovskiy horizon) is 26 m thick and consists of light-gray and white limes which are highly recrystallized and highly silicified, and which contain flint-inclusions and clay-admixtures. With regard to fauna crinoid-foraminifera-limes predominate, those containing brachiopods and other fossils of animal groups are more seldom represented. The foraminifera fauna makes assume an analogy with the Molotovskiy horizon, but the Pseudostafella are too scarce for this. On the other hand the occurrence of

Card 1/3

Deposits of the Bashkirskiy Stage in Melekess

20-2-5a/6a

differences of the fauna stand in the complexes render their assimilation difficult. Nevertheless the upper complex may be equated with the upper part of the Podvereyskiy horizon (according to the first occurrence of Aljutovella and Verella). The first occurrence of Schubertella here might be explained by its belated penetration to this part of the water. Thus only the upper half of the sediments of the Bashkirskiy stage is apparently present in the Melekess. There is no gap between the Bashkirskiy- and Vereyskiy sediments, here. The Bashkirskiy sediments at the right bank of the Volga approximately have a similar extension in the Uljanovskiy support bore-hole, but the thickness here decreases toward the west to 25 m and still further. These facts reflect the existence of apparently large elevations during the Carboniferous.

COVERAGE: The collection contains papers reviewing the development of open-hearth steelmaking theory and practice. The papers, written by staff members of schools of higher education, scientific research institutes, and main laboratories of metallurgical plants, were presented and discussed at the Scientific Conference of Schools of Higher Education. The following topics are considered: the kinetics and mechanism of carbon oxidation; the process of slag formation in open-hearth furnaces using in the charge either ore-lime briquets or composite flux (the product of calcining the mixture of lime with bauxite); the behavior of hydrogen in the open-hearth bath; metal desulfurization processes; the control of the open-hearth thermal melting regime and its automation; heat-engineering problems in large-capacity furnaces; aerodynamic properties of fuel gases and their flow in the furnace combustion chamber; and the improvement of high-alloy steel quality through the utilization of vacuum and natural gases. The following persons took part in the discussion of the papers at the Conference: S.I. Filippov, V.A. Kudrin, M.A. Glinkov, R.P. Nam, V.I. Yavoyskiy, G.N. Oyks and Ye. V. Chelishchev (Moscow Steel Institute); Ye. A. Kazachkov and A. S. Kharitonov (Zhdanov Metallurgical Institute); N.S. Mikhaylets (Institute of Chemical Metallurgy of the Siberian Branch of the Academy of Sciences USSR); A.I. Stroganov and D. Ya. Povolotskiy (Chelyabinsk Polytechnic Institute); P.V. Umrikhin (Ural Polytechnic Institute); I.I. Fomln (the Moscow "Serp i molot" Metallurgical Plant); V.A. Fuklev (Central Asian Polytechnic Institute)

 Title : Sunflower Sowing Periods and Beds in Siberian Districts

Orig. Pub. : V sb. Kaslichn. kul'tury v vost. r-nakh SSSR. Krasnodar, "Sov. Kuban'", 1956, 108-117

Abstract : Mid season planting of sunflowers is practical on the weeded plots in Siberia; weeds do not reduce the harvest in comparison with early planting and note it possible to destroy the weed shoots by preplanting cultivation. Midwinter sowing can be recommended only as an expedient. The best space kept between the rows should be considered 70 cm for the sunflowers in the districts of Siberia. Narrower spaces do not increase the yield and make mechanized care difficult. In

Orig Pub : Byul. nauchno-tekhn. inform. Vses. n.-i. in-t maslichn. i efiromaslichn. Kul'tur, 1957, No 3, 21-23  
Abstract : Deep cultivation (12-16 centimeters) does not produce an increase in the yield since it leads to a severe desiccation of the soil. Shallow cultivation (6-10 centimeters) can be carried out with the smallest protective zone (8-10 centimeters) without a considerable injury to the root system. It secures the undercutting of the weeds and creation of a loose upper layer which protects the soil from excessive evaporation.

**Devices for the Removal of the Products of Combustion from Open-Hearth Furnaces.** I. Semikin and L. Segun. (Stal, 1938, No. 5, pp. 30-35). (In Russian). The authors discuss the characteristics of the methods used to provide the draught necessary for the removal of the products of combustion from open-hearth furnaces. The ordinary chimney, the indirect- and direct-acting forced-draught flue and the direct-acting forced-draught flue combined with a boiler to utilise the waste-heat of the gases are discussed. The latter is regarded as being the most advantageous and reliable. Each furnace should be provided with two such boiler equipments, one being in reserve. Finally a scheme is suggested for the centralisation of the draught system of a number of open-hearth furnaces which could thus be combined with a central waste-heat boiler plant.

PROCESSES AND PROPERTIES INDEX

210

**The Design of Open-Hearth Furnaces for Increased Production.**  
 I. Semikin. (Stal, 1939, No. 9, pp. 16-19). (In Russian). Large capacity (300-350 ton) furnaces are capable of producing up to 1000 tons of steel in 8 hr. For this it is necessary to increase the heat supply during the charging period to 50-60 million cal. per hr. using forced draft at a pressure of 100-150 mm. of water. Utilization of the heat of the flue gases for steam raising is possible. The furnace should be made gas-tight by a steel shell. Gas and air uptakes and slag pockets and regenerators should have individual walls. Spaces between slag pockets and regenerators should be ventilated. The author discusses more particularly, and with some reference to experimental data and works experience, the design of the bath and the volume of the furnace, methods of supporting the furnace structure, port design, slag pockets, regenerators, reversing valves and flues.

Thermal work in reverberatory furnaces. I. D. Sankin and M. D. Shabl. *Soviet Metal.* 14, No. 3: 21-25 (1930); *Chemie & Industrie* 42, 821. The chief reason for the low efficiency of existing reverberatory furnaces lies in their insufficient thermal power. The optimum thermal power of these furnaces is 50-60 million cal. per hr., or about 300,000 cal. per hr. per sq. m. of hearth area, corresponding, for a 180-sq.-m. furnace, to a production of 1000 tons of Cu per 23 hr. with a heat consumption of 800,000 cal. per ton. It is necessary to modify the heat balance of the furnaces so as to obtain complete and intense combustion of the fuel over as short a distance as possible. A. Panneau-Contine.

Prof I. D. Semikin, Dnepropetrovsk Metal Inst; I. G.  
Polovchenko, Engr, Dneprodzerzhinsk Night Inst, 8 pp

"Stal'" No 12

Authors discuss new construction for hearths of  
blast furnaces. Hearth has heavy bronze base under  
the hearth block. Cooling plates are arranged under  
the hearth block. Claim that with this arrangement  
stability of hearth is increased, service period of  
hearth block and foundations is lengthened, and  
operating period of the furnace increases.

TITLE To the Theory of the Free Jet (K teorii svobodnoy strui)

PERIODICAL Nauch. tr. Dnepropetr. metallurg. in-ta, 1954, Nr 31, pp 3-15

ABSTRACT Differential equations are obtained, which determine the propagation of a plane and an axisymmetrical laminar jet in an infinite medium having the same physical properties. Formulas for the velocity distribution over a cross section and along the axis of the jet are given. It is shown that the dimensionless velocity profiles become similar, starting from a certain fully defined time criterion. The calculations conducted on the basis of the relationships obtained are confirmed satisfactorily by the experimental data of I. D. Semikin (Nauch. tr. Dnepropetr. metallurg. in-ta, 1948, Nr 14). However, it is necessary to note that the formulas proposed by the authors coincide with the first approximation of the solution obtained for similar problems earlier by Pai, S. J., (Mekhanika, Sb. Perv. i obz. in. period. lit. 1950, Nr 1; Quarterly Appl. Math., 1952, Vol 10, Nr 2).

TITLE: The Laws Governing the Combustion Process of a Gas in a Torch Flame (Zakonomernosti fakel'nogo protsessa szhiganiya gaza)

PERIODICAL: Nauch. tr. Dnepropetr. metallurg. in-ta, 1955, Nr 33, pp 83-103

ABSTRACT: The velocity distribution in the various sections, the velocity variation along the axis, the gas-flow rate across the cross section, and the diameters of the cross section of the jet are determined by means of G.N. Abramovich's equations of the theory of the turbulent gaseous jet [Prikladnaya gazovaya dinamika (Applied Gasdynamics), Gostekhizdat, 1953] for values of the empirical coefficient  $a = 0.080 - 0.085$ . A correlation of the calculated and the experimental data establishes the effect on the length of the flame of the inner diameter of the torch (the nozzle diameter), the heat value of the fuel, the  $O_2$  content of the air, and the excess air. Empirical formulas for the flame length are compiled with and without consideration of the

entrance velocity of the gas and the air, and the temperature of the gas and the air. The effect of the crowding of a flame and the angle of convergence and distance between flames are examined only qualitatively.

TITLE. Controlling the Flame Jet in Open hearth Furnaces (Organizatsiya fakela plameni v martenovskikh pechakh)

PERIODICAL Tr. Donetsk. otd. Nauchno-tekhn. o-va chernoy metallurgii, 1957, Nr 5, pp 39-46

ABSTRACT When a free jet moves in an infinite space, the process of mixing consists of the capture of and transportation of the necessary amount of air into the depth of the flame and then of intimate intermixing thereof. The flame length (FL) depends upon the diameter of the burner, the heating value of the gas (calculation has to be in terms of heat value per unit weight), the O<sub>2</sub> content of the air, the velocities of the gas and air flows and the angle at which they meet. In open-hearth furnace practice, FL is not dependent upon the velocity of the gas, unless supplementary sources of energy are used in the form of compressed air. But the FL does depend upon air velocity, declining as air velocity increases. The angle of contact of gas and air must not be  $>20^{\circ}$ , because although the FL diminishes

### Controlling the Flame Jet in Open Hearth Furnaces

in this case as the result of the impact of the flows, the aerodynamics of the flame are simultaneously impaired. Venturi ports should be modified in the following directions: 1) reduction of the dimensions of the gas port where reserve draft is available, 2) provision of multiple-jet burners if coke gas is available. The speed of outflow of cold coke gas should be  $\geq 80$  m/sec; 3) delivery of compressed air in high-pressure jets with Laval nozzles. It was found at one of the plants in Dnepropetrovsk that delivery of compressed air into the tank by means of two side nozzles reduced heat time by 30-40 min. A design has been developed of a port with an aerodynamic tank in which the major role is played by air and not gas.

TITEL: On the technical indices of open hearth furnace operation  
(As a discussion)

PERIODICAL: Izvestiya bysshikh uchebnykh zavedeniy. Chernaya metallurgiya,  
no. 12, 1960, 139 - 145

TEXT: The article deals with the problem of determining the output quota for open-hearth furnaces. The present methods are criticized with reference to the author 's own three works [Ref. 1: I. D. Semikin. Diskus-siya o rabote domennykh pechey na povyshennom davlenii (Discussion on Blast Furnaces Operating on Higher Pressure), NTO ChM, Dnepropetrovsk, 1958; Ref. 2: I. D. Semikin. A161/A133

The authors emphasizes that the output capacity of a furnace depends on design as far as design results in a lower or higher heat capacity, i.e. a furnace will give a high output if its design permits the combustion of more fuel without ruining the brickwork, and the design of the head affecting the flame in the furnace is the most important design factor at the moment. He does not agree with the opinion of some metallurgists that low efficiency is inherent in large furnaces. Three factors are suggested to serve as a basis of productivity rating: I - The furnace heat capacity,  $M_{05}$  ( $M_{gen}$ ), with metal output per 1 million calories (as the electro-metallurgists use to set the output quota by the furnace transformer capacity), though the maximum heat capacity depends on the designer's understanding of its importance. The higher the maximum heat power, the higher will be the absolute productivity, but the specific output per 1,000,000 cal will be gradually lower, and intensely operating furnaces will have a lower specific output index (which will not stimulate rational development). II - The furnace charge (E), for it is easily controllable. The annual furnace capacity would than be determined by the number of heats (n) per year:

$$P = nE,$$

Card 2/4

On the technical indices of open hearth...

S/148/60/000/012/016/020  
A161/A133

though it would depend on the heat capacity, the charge weight, the number of work days a year, form of charge (liquid or cold iron), steel grade, etc, and would be possible for certain average conditions only (which is true for any methods). Besides this, a correction factor would have to be used, since the annual number of heats depends on the charge volume, and 12 - 16 heats a day are possible in a 5-ton furnace, and only 3 - 4 in 500-ton furnace. III - The furnace hearth area (F), or, actually, the metal bath surface area. This factor is just the index being used now, and the output per 1 m<sup>2</sup> of floor permits a comparison of furnaces of different sizes. It would be practical in the first approximation, but it has a negative side as well. The hearth area is not as dependably determinable as the charge E, and fair comparison of capacities would only be possible taking into account the real bath surface level. This is so for two reasons: 1) Designers want to conceal the real hearth area to get a "high" output index, and indicate excessive furnace wall thickness in drawings. Such thick walls are rapidly destroyed by slag (after 10 - 15 heats) in a narrow furnace, the width and the metal surface area become normal, but the metal output is still related to the smaller initial floor area; 2) Being of the opinion that the heat process is the faster the shallower the bath is, designers

TITLE: A heat radiation calorimeter

SOURCE: Ukraine. Gosudarstvennaya planvoya komissiya. Institut  
avtomatiki. Avtomatizatsiya i priborostroyeniye; sbornik  
nauchnykh trudov, no. 2, Kiyev, 1961, 153-164

TEXT: The authors describe a thermal radiation calorimeter based on the principle of temperature difference produced at a neat resistance by the thermal flux. The instrument consists basically of a hollow copper cylinder with a partition in its middle. The thickness of the cylinder walls and of the partition does not exceed 0.2 mm. The part of the cylinder above the partition acts as an absolutely black body and performs the function of a heat collector. The lower part of the cylinder is slotted, the slots acting as thermal resistances. The cylinder has a connection sleeve for the wiring of a thermocouple battery. The battery is made of copper-constant thermocouples, whose number is determined by the sensitivity

Card 1/3

X

S/704/61/000/002/006/006

A heat radiation calorimeter ...

of the instrument. The thermocouple battery is wound at the external cylinder surface in such a manner that the heat resistances be placed between the thermocouple junctions (hot junctions) placed against the surface of the heat collector and the junctions placed at the water-cooled part of the cylinder (cold junctions). The junctions are isolated from the cylinder surface by mica wafers. Mica is also used to insulate the thermocouples from the top. The heat collector, together with the thermocouples is placed in a protective envelope. A mirror-polished nickel foil is placed between the collector and the envelope; this arrangement makes the heat losses negligible. The whole arrangement is assembled into a separate unit, fixed at the face of the water-cooled bloc which at its other end has two pipes for the circulation of water and one for the wiring from the thermocouple battery to a potentiometer. The experiments have shown the linear dependence of the e.m.f. of the radiation calorimeter on the thermal flux; the temperature of the radiating body  $T_r$  was found to satisfy Eq. (17)

TITLE: Basic mechanism of a turbulent gas flame  
PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy.  
Chernaya metallurgiya, no.4, 1962, 140-152

TEXT: The paper is a continuation of previous work. The similarity conditions in turbulent flow are analysed and a formula derived for transforming from one type of flow to another. The length of the flame is regarded as the sum of two lengths, the capture length in which the gas emerging from the nozzle captures some of the surrounding air and the transfer length in which the combustion is completed. The forces in the flame due to the difference between the densities of the gases, and the dimensionless Euler forces arising from the differences in static pressure are evaluated and a calculation made of the amount of air transferred in the capture length. A fifth power equation is obtained for the dimensionless length of the turbulent flame and the factors determining this length are briefly discussed.

AUTHORS: Averin, S.I., Semikin, I.D.

TITLE: Combustion of a single component gas mixture in a turbulent flame

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya metallurgiya, no.6, 1962, 146-154

TEXT: In a previous work (Izv.VUZ. Chernaya metallurgiya, no.4, 1962) the present authors found the formula for flame length

$$Z_{0\phi_{\text{ак}}} = \left[ N_0(1+G) - \frac{1}{b_0} \right] \sqrt{\frac{\gamma_r}{\gamma_{\text{см}} \left( 1 + \frac{i(G) \cdot i(\tau)}{Fr} Z_{0\phi_{\text{ак}}}^3 \right)}}, \quad (1)$$

In order to calculate flame length from this formula, it is necessary to know the mean composition and specific gravity of the gas mixture at the end of the capture path, and equations are quoted for (1) the weight fractions of combustible gas, of residual  
Card 1/2

Combustion of a single ...

free oxygen, of the products of the reaction, of nitrogen and of unburnt gas; (2) the specific gravity of the gas mixture and (3) the mean temperature of the gas mixture. These formulae are applied to calculating the composition, thermal characteristics, specific gravity and flame length in the combustion of hydrogen and carbon monoxide; the results are shown in tabular and graphical form. The analysis is applicable to complex multi-component gas mixtures and gives good agreement with experiment. There are 6 figures. ✓

TITLE: The combustion of multicomponent gas mixtures in a turbulent flame

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy. Chernaya metallurgiya, no.8, 1962, 158-169

TEXT: General equations are first formulated for the combustion of a mixture of two combustible gases with oxygen. The combustion of mixtures of oxides of carbon and hydrogen is then considered and, on the basis of previous articles by the same authors (Izv.VUZ. Chernaya metallurgiya, nos. 4 and 6, 1962), a formula is derived for the ratio of the flame length to the gas nozzle diameter. An auxiliary graph is given to facilitate practical calculations with the formula. The combustion of hydrocarbons and of mixtures of several gases is then considered. Calculations are made of flame length as function of Froude Number for oxides of carbon, hydrogen, generator gas, natural gas, coke oven gas, blast furnace gas and Moscow city gas in an atmosphere of air for subsonic rates of gas flow. The results are compared with Card 1/2

The combustion of ...

S/148/62/000/008/008/009  
E194/E435

published experimental data and agreement is good. The method can be used to assess the influence of various factors on flame-length. It is found that on burning mixtures of carbon oxides with hydrogen the flame length increases with the hydrogen content. When burning mixtures of hydrogen and hydrocarbons, and in particular with methane, the flame-length increases with the concentration of hydrocarbons. When burning mixtures of methane with hydrocarbons of the series  $C_nH_{2n+2}$  the flame-length increases as the methane concentration is reduced and the concentration of  $C_nH_{2n+2}$  hydrocarbons is increased. There are 3 figures. ✓

TITLE: Length of a turbulent gas flame issuing under high pressure from cylindrical and conical jets

PERIODICAL: Izvestiya vysshikh uchebnykh zavedeniy, Chernaya metallurgiya, no.12, 1962, 162-173

TEXT: A formula for turbulent flame length derived previously by the present authors (Izv. vuz. Chern. met. no.8, 1962) is analysed and developed with special reference to conditions of high gas velocity, in which changes of gas density must be taken into account. The relationship between the specific gravity and the velocity of the gas is established, and two criteria, characterising respectively the relative gas flow and the initial gas compression, are obtained. Calculations are carried out for Shebelinka natural gas (92.3% CH<sub>4</sub>, 4.21% C<sub>2</sub>H<sub>6</sub>, 0.9% C<sub>3</sub>H<sub>8</sub>, 0.33% C<sub>4</sub>H<sub>10</sub>, 0.46% C<sub>5</sub>H<sub>12</sub>, 1.39% N<sub>2</sub>, 0.41% CO), and curves are given to show the dependence of flame length on relative gas flow. The flame length increases continuously with increasing gas flow, but at a decreasing rate up to a critical flow, after which the rate.

Card 1/2

Length of a turbulent gas flame ... S/148/62/000/012/008/008  
E081/E184

increases again. Smaller diameter jets give shorter flames with a greater ratio of flame length to jet diameter. If the air is pre-heated, the flame length increases more rapidly with gas flow than if it is not; the flame length to jet diameter ratio depends less on jet diameter and the flame is longer. Measurements made with Shebelinka gas show good agreement with theory. There are 6 figures.
