1427. SIMON M. and DAN S. *Esterasevizsgálatok pemphigus és dermatitis herpetiformis Duhring eseteiben. Examinations of the effect of esterase in pemphigus and dermatitis herpetiformis BÖRGYÖGY. VENER. SZLE 1954, 30/5 (134-136) Graphs 1 Tables 2

The authors examined the esterase activity in 78 cases, suffering from different diseases. In pemphigus and dermatitis herpetiformis the esterase activity was very low. The activity of esterase increased with the clinical improvement and declined with relapse of the diseases. The phenomenon can be used for the prognosis also. Vámos - Budapest

Evaluation of personal case material showed that 48 patients with carcinoma on lupus vulgaris lesions constituted 8.51% of the total lupus material. The basic disease usually appears between the 10th and 30th yr. of life. The carcinoma developed after an average of 24 years' existence of the basic disease. In 85% carcinoma on lupus vulgaris was localized in the head, in 5% on the neck and in 10% in the extremities. Previous X-irradiation in therapeutic doses does not play a significant role in the development of carcinoma on lupus vulgaris. Modern chemotherapy will probably lead to a considerable decrease of the frequency of lupus and of the carcinoma secondary to it.

SOURCE: Academia scientiarum hungaricae. Acta microbiologia, v. 12, no. 2, 1965, 123-130

TOPIC TAGS: epidemiology, virus, virology, virus disease

ABSTRACT: Systematic serological and virus isolation studies were made during the keratoconjunctivitis epidemic (Dec. 61-Sept. 62) in Budapest and during the subsequent 1 1/2 years without epidemic. An attempt at virus isolation was made with 51 clinical specimens collected during the epidemic. One of these yielded type 3 and four of them yielded type 8 strains of adenovirus. Serological examinations (hemagglutination inhibition, complement fixation) have shown that 63 per cent of the cases were caused by the type 8 adenovirus during the epidemic period. Isolation experiments, using 93 different specimens obtained from 81 clinical cases of keratoconjunctivitis observed in the non-epidemic period, yielded adenoviruses of different types (3, 4, 7, 14 and 16) and also Herpes simplex virus. The results of the isolation experiments were confirmed by serological testing. During the non-epidemic period, only about 15 per cent of the keratoconjunctivitis cases were caused by type 8 adenovirus. The authors thank Doctor E. Farkas and Doctor I. Domok for their help and valuable criticism. They also thank Mrs. Z. Kiss, Miss E. Schneider, and Mrs. G. Gaspar for excellent technical assistance. Orig. art. has: 1 figure and 3 tables. JANCSO, Agnes, Dr, SIMON, Miklos, Dr; National Public Health Institute (chief director: BAKACS, Tibor, Dr) (Orszagos Kozegeszsegugyi Intezet), and Health Service of the Hungarian People's Army (Magyar Nephadsereg Egeszsegugyi Szolgalata), Budapest.

"Epidemic and Sporadic Cases of Keratoconjunctivitis."

Budapest, Orvosi Hetilap, Vol 107, No 32, 7 Aug 66, pages 1499-1502.

Abstract: [Authors' Hungarian summary] There was an epidemic of keratoconjunctivitis in Budapest, between Dec 1961 and Sep 1962. Blood sample tests (HAG and Kk) of the patients revealed that 63 per cent of the cases were caused by adenovirus type 8. During the period free of epidemics, however, other types of adenovirus (3, 4, 7, 16) and the herpes simplex virus also played a role in the etiology of the 81 cases of keratoconjunctivitis studied. Only 15 per cent of these cases were caused by adenovirus type 8. 9 Hungarian, 16 Western references.

Histochemical investigations on the action of BAL on the excretion of arsenobenzene. St. Pastinarky and N. Simon (Univ. Clinic Skin and Venereal Diseases, Debrecen, Hungary) *Dermatologica* 100, 87 (1949) (in German). After injection of arsenobenzene in albino mice and rats, there was rapid renal excretion which was even more rapid after treatment with BAL. Storage: BAL mobilized the arsenobenzene reticulo-endothelial system; BAL mobilized the arsenobenzene debris which were excreted by way of the kidneys. In the controls, the As content of the organs remained high and little or no As was excreted. The As content of the skin was high but no As was demonstrated in the walls of the gall bladder and the salivary or mammary glands.

1369. SIMON N. and DÁN A. *Esterasevizsgálatok pemphigus és dermatitis herpetiformis Dühring esetében. Examination of esterase in pemphigus and dermatitis herpetiformis HUNG. DERM. VENER. REV. 1954. 30 (134)

The authors performed 78 examinations of esterase activity on patients suffering from different dermatological diseases, e. g. the pemphigus group. The esterase activity in psoriasis, erythematous, eczema and in skin-tb cases scarcely diverged from the normal values, while in cases of the pemphigus group the esterase-activity values were significantly lower. In pemphigus and dermatitis herpetiformis the values of esterase activity decrease and increase parallel with the deterioration and amelioration of the state.

195. SIMON N., GAVALLER I. and SURANYI S. Dermatol. und Geburtsh. Gynakol. Univ.-Klin., Debrecen. Über den Pathomechanismus der Tuberculosis indurativa (Bazin) *The pathomechanism of tuberculosis indurativa (Bazin)* Hautarzt 1956, 7/6 (253-257)

In 39 women with Bazin's disease and 110 women with genital tb the pathogenetic motives responsible for a connection between the 2 processes were investigated. The possibility that in Bazin's disease the dissemination of bacilli originates from a genital or endometrial tb, could be excluded by corresponding examinations (a.o. bacteriological and histological). In 110 women with histologically verified genital tb Bazin's disease did not occur more frequently than the other manifestations of skin tb. On account of the present findings genital tb or tb endometritis should not be considered to be of greater significance in the genesis of Bazin's disease than other tuberculous diseases. However, it is probable, that in both forms of disease neuro-endocrine disturbances play a role, as hyperthyreosis, hypoplastic genitals, oligomenorrhoea, amenorrhoea, possible positive menstrual disturbances, fluor, infantilism on one side, keratosis pilaris, hypertrichosis, erythrocyanosis cruris puellarum on the other side. In the above-mentioned conditioned motives, circulatory disturbances of the lower leg and increased distress of the leg become predisposing factors, which make possible the nidation of tubercle bacilli, disseminated over any foci in the organism, in the lower leg, and so lead to the appearance of the characteristic phenomena of Bazin's disease.

1014. THE AGE OF PREDISPOSITION FOR LUPUS VULGARIS AND TUBERCULOSIS COLLIQUATIVA CUTIS - über das Prädispositionsalter für Lupus vulgaris und Tuberculosis colliquativa cutis - Simon N. and Csoka I. Univ. -Hautklin., Debrecen - Z. HAUT- U. GESCHL.-KR. 1958, 24/2 (42-51) Graphs 2 Tables 6 Illus. 8

Correlation between patient's age and the onset of tuberculous diseases of the skin was looked for in the material of the Dermatological Clinic in Debrecen. With the Wilcoxon method as further developed by Rényi, it was found that the onset of all tuberculous skin affections and of tb cutis coll. occurred significantly more often under 40 yr. than over this age. For lupus, no such significant correlation could be found - probably because of the small number of cases. The age-frequency curves of lupus vulg. and tb cutis coll. are discussed and compared (XIII, 15)

Case report of a nodose infiltrating form of tuberculosis subcutanea fistulosa. The

1448

condition is believed to be due to autogenous infection, in which the mycobacteria entered the perirectal tissue through a previously existing fistula. In this case the combined long-term therapy with INH and PAS led to disappearance of symptoms. Notwithstanding clinical, extensive branching fistulas could be shown in the subcutis by means of injected contrast media. The tuberculosis subcutanea fistulosa is said to belong to the group of tuberculosis colliquativa cutis.

...
tion at the Hidac mine ...
Művelődés és Iskolák Közlönye - P. Simon (Hungarian
Journal of Mining - *Bányászati Lapok* - Vol. 7(25),
1952, No. 12, pp. 665-668)

At the Hidac Mine it became necessary to drive a gallery of 3.6 m dia through clay soil which was wetted by water from a borehole and a layer of gravel. Due to the effect of the water the clay took on a swollen and sticky consistency. The usual stake driving method was unsuccessful, therefore, on the basis of previous tests, it was decided to apply the electrochemical consolidation process. Anodes were driven to a depth of 10 m and filled with 4 kg of chemicals by means of compressed air. 100 V d.c. served as a source of current. This method proved efficient. No free water could be observed in the cross section of the gallery and the working of the clay layer was easily accomplished. The pressure ceased completely. Later the gallery was driven from two sides with four electrodes each behind the walling. The desired target was also achieved by this method. P. Simon

38. Characteristics of selenium rectifiers in static and service connections -- *Szelénegyenirányítók jellegeté-
beli statikus és üzemszerű kapcsolásiban* - S. Simon. (Elec-
trical Engineering - *Elektrotechnika* - Vol. 8 - No. 5,
May 1952, pp. 154-159, 6 figs.)

The rectifying elements are evaluated according to their properties. However, it is also necessary to know the effects of changes in feeding voltage, load and voltage drop due to increased specific load as a consequence of artificial cooling, etc., which can be determined from the characteristics. Methods of measurement furnishing data that may be reproduced at any time are described. The results of measuring connections in a forward direction, measurements with a smooth d. c. and a single-phase rectifying device with a bridge circuit used as a source of power are discussed. A description is rendered of measuring with pulsating direct voltage, of switching in a. c. to the rectifier plate, of determining the average values and measuring circuits for a backward direction.

✓ The nitrogen and carbohydrate metabolism of *Actinomyces globisporus streptomycini*. S. Simon (Forschungsinst. Pharm. Ind., Budapest). *Acta Microbiol. Acad. Sci. Hung.* 3, 341-52(1956)(In German).—*A. globisporus streptomycini* was grown in glass containers in cultures of 10-25 l. or industrial (steel) fermentors of 10 m.³ Data are shown of the glucose (or sol. carbohydrate hydrolyzable to reducing sugar), NH₃, org. N, pH, and streptomycin at intervals during the course of these fermentations. The culture medium contained 2% soybean meal, 2% glucose (or starch), 0.4% corn-steep liquor, and 0.1% CaCO₃ (cf. C.A. 50, 7226c). After the available carbohydrates are consumed an abrupt increase in the NH₃ content of the culture soln. occurs. Frequently the org. N decreases but little in the first 1-3 days of the fermentation, but in the autolysis stages it increases. When the medium is made with lightly roasted soybean meal, carbohydrate utilization is lessened and there is a persistent increase in the reduction of the sol. N if the yields are high. When strongly roasted meal is used, the utilization of N is not increased, carbohydrate utilization is increased and the yield of streptomycin increases. Stachyose, raffinose, and sucrose were found not to be available to the organism used. There is increased carbohydrate utilization and a rapid increase in org. N in reference to small shake cultures. The pronounced increase in the NH₃ content generally did not occur and the pH of the medium remained considerably less alk. The organism released an extracellular protease into the medium. E. L. Green

TITLE: Utilization of oils with a high sulfur content in blast furnaces

SOURCE: Kohaszati lapok, v. 98, no. 1, 1965, 21-26

TOPIC TAGS: blast furnace, slag, iron, radioisotope, pig iron, sulfur, mineral oil

ABSTRACT: Plant experiments were conducted at the Metallurgical Works (Kohaszati Uzemek) in Ozd to establish the distribution of the sulfur contained in the oil injected into the blast furnace between the slag and the crude iron. Hungarian oils, containing 3-4% sulfur, were evaluated with the aid of radioactive sulfur isotopes. Assistance in the project was provided by the Laboratory for Radioactive Isotopes at the Chair for Ferrous Metallurgy, Technical University for the Heavy Industry (Nehezipari Muszaki Egyetem Vaskohaszattani Tanszekenek Radioaktiv Izotoplaboratoriuma) [location not given]. The tests showed that the injection of oil containing high quantities of sulfur did not significantly affect the sulfur content of the pig iron. Orig. art. has: 4 figures, 3 formulas, and 9 tables. u

The distribution of amino acids in the blood in anemia. SANDOR SIMON AND IURAN CSOMAY. *Magyar Orvosi Arch* 32, 202 (1931). A study was made of the distribution of amino acids between corpuscles and plasma of normal and of anemic human and animal bloods. The colorimetric method of Folin was used. In anemia the amino acid content of red blood cells is either high or normal (with maximal figures). The ratio corpuscle amino acid to plasma amino acid is always increased in anemia. The amino acid contents of plasma and whole blood are unchanged. During the time of regeneration the corpuscles amino acid and the above ratio decreases. The organism shows a tendency to distribute amino acids at the same rate between plasma and corpuscles.

Ujabb farmakologiai vizsgalatok alkoholos vizeletkivonatokkal Recent Pharmacological experiments with alcoholic extracts of urine Orvosi Hetilap 1948, 89/529-544 (540-542) Graphs 3 Tables 1

According to earlier experiments (Naunyn-Schmiedeberg's Arch. 1944, 197, 370; 198, 528; 203, 171) alcoholic extracts of the urine, evaporated in vacuo, cause significant increase of blood pressure after an initial decrease. This phenomenon is not due to known substances (renin, vagotonin, etc.). Recent experiments exclude the participation of ammonis, histidine and creatine in this effect. The effective substance is not destroyed by pepsin or hypertensinase. An extract corresponding to 4-8 ml. of well-purified urine causes spasm and paralysis of respiration when administered to mice intravenously. In case of slow injection, the effect passes off quickly and the mice remain alive. The extract paralyzes the spontaneous contractions of the isolated uterus of the rat.

TITLE: Biological assay of vitamin D using microscopic estimation of calcified
cartilage in rats with rickets 22

SOURCE: Academia scientiarum hungaricae. Acta physiologica, v. 28, no. 3,
1965, 287-294

TOPIC TAGS: nutrition disease, vitamin, rat, histology

ABSTRACT: The microscopic measurement of the diameter of calcified cartilage has
been undertaken to estimate the degree of healing in cases of rickets in rats. A
section of the bisected radius and ulna was treated with silver nitrate,
placed in two parallel grooves of Burker's erythrocyte counting chamber,
and then covered with a special cover-slip 2.5 mm thick and marked
into 0.1 mm² squares. Burker's chamber was then placed on the stage of a
microstereoscope of 50 magnification. The diameter of the fresh calcifica-
tion was determined at 7 points and the results were averaged. Such
measurements are easiest to make in the initial phase of healing. The curve
depicting the effect of 0.25-4.0 units of vitamin D₃ showed a linear regression.

measured 12 hours after the administration of dextran, as related to that found after reinfusion of blood, was on the border of significance. The 12-hour mean blood pressure values measured both in the dextran and polyvinylpyrrolidone series were much lower than the means before blood withdrawal. The survival rate was higher in the dextran series. Reinfusion of the animal's own blood maintained the mean blood pressure at a normal level throughout, when the dose of heparin was low. Survival was best in these cases. When high doses of heparin were used, blood pressure was readjusted to much lower levels. Circulating blood volume was lower even 6 hours after the administration of polyvinylpyrrolidone than six hours following treatment with dextran. The same applied to the six- and 12-hour values. The effect of the Polish dextran preparation used in most experiments was of the same order of magnitude as that of the Hungarian and the American Expandex preparation. Alcoholism and B₁ vitamin deficiency. *East. J. Med. and Tibor Simon, Orvosi Lapj 4, 62-3:1948; cf. C. I. 40, 7335.* - Polyneuritis is often a symptom of chronic alc. intoxication; probably vitamin deficiency may also play a role. In clinical load tests often severe vitamin-B₁ deficiencies were observed without any signs of neuritis. Clinical expts. were conducted with vitamin B₁ loads on alcoholic persons. Also the amts. of substances binding bisulfite were detd. according to the method of Chitt and Cook as modified by Laszt. Most alc. persons showed vitamin deficiency; the excretion of vitamin B₁ during the load test was, on an av., 10.3% as against 21.1% for persons satd. with vitamin. Simultaneously, the amt. of bisulfite-binding material increased significantly; it showed a mean value of 11.4 mg. % against 8.2 mg. % for satd. persons. Nine persons out of 12 belonged to the first group, proving that not only vitamin B₁ deficiency but also the toxic effect of alc. plays a role in the etiology of alc. polyneuritis. István Földi

Abstract: [Authors' Hungarian summary] The catamnestic data of 210 patients suffering from congenital heart defect were compared with a healthy control group. On the basis of the investigation, the following parameters are thought to be of pathogenetic importance in the development of congenital heart defects. 1) Advanced age of the parents, especially of the father, 2) excessive consumption of drugs by the mother in the early phase of pregnancy, 3) viral infections during early pregnancy, influenza, e.g., 4) psychic trauma suffered in the early stage of pregnancy. The results obtained are compared with the available literature data. 14 Hungarian, 23 Western references.
