TITLE: The cross section of quark generation

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki. Pis'ma v redaktsiyu. Prilozheniya, v. 3, no. 8, 1966, 340-344

TOPIC TAGS: quantum electrodynamics, strong nuclear interaction, nuclear cross section, collision cross section, quark

ABSTRACT: The authors show that both independent experiment and the theory yield for the quark generation cross section a value some 5 orders of magnitude larger than would follow from estimates based on the absence of quarks from pN collisions in accelerators or cosmic rays. The basic assumption is that at the particular interaction distances the qN or q π (q = quark) interaction is essentially the usual one for NN and π N. The dependence of the cross section for the generation of pairs of heavy strongly-interacting particles on their mass can be deduced from accelerator experiments on the generation of \bar{p} (antiprotons) and \bar{d} (antideuterons), and also $\bar{\Sigma}^-$ and $\bar{\Lambda}_1^*$. From an estimate of the ratio of the ratio of their numbers $n_{\bar{p}}$ and $n_{\bar{d}}$

Card 1/2

L 21808-66
ACC NR: AP6012192

to the number of pions n_π in the p-Be collision act (which is practically the same as for the pN collision) it is possible to estimate the generation cross sections σ_p and σ_d in pN collision, and from them the cross sections and the number of the quarks. A theoretical justification for the estimate is given. As an example it is indicated that even for very large $n_\pi \sim 500$, for example in collisions of a Ca nucleus with energy $E_{lab} > 10^{12}$ ev/nucleon in emulsion, the estimate yields $n_q \sim 12, 0.6 \times 10^{-3}$, and 1×10^{-9} for $m_q/m_N = 1, 2$, and 3 , respectively. The relation derived theoretically is general and shows that the decay of any excited center into pions is always more convenient than other processes. The same holds also for electric generation, and in general for any diagram vertex in which a $q\bar{q}$ pair is produced. Orig. art. has: 1 figure and 2 formulas.

AUTHOR: Sisigina, T.I.TITLE: Spectral Composition of the Gamma-radiation of Elements
of the Uranium and Thorium Family (Spektral'nyy sostav
gamma-izlucheniya elementov semeystva urana i toriya)PERIODICAL: Izvestiya Akademii Nauk SSSR, Seriya Geofizicheskaya,
1957, No.12, pp. 1484 - 1490 (USSR).

ABSTRACT: On the basis of analysis, of published data relating to gamma-radiation of elements of the uranium and thorium family, tables are compiled of the spectral composition of the gamma-radiation of the elements of these families. The energy characteristics are calculated of the gamma-radiation of the elements of the uranium and thorium family and the full energy of the gamma-radiation is determined for uranium, thorium and radium in the states of equilibrium. The information given in the paper can be useful in solving problems of gamma-spectroscopy relating to the study of the radio-activity of rocks. There are 1 figure and 8 tables and 19 references, 3 of which are Slavic.

Karol', I. L., and S. G. Malakhov, Candidates of Physics and Mathematics, eds.

Voprosy yadernoy meteorologii; sbornik statey (Problems in Nuclear Meteorology; a Collection of Articles) Moscow, Gosatomizdat, 1962.
271 p. Errata slip inserted. 2600 copies printed.

Ed.: A. I. Zavodchikova; Tech. Ed.: Ye. I. Mazel'.

PURPOSE: The book is intended for meteorologists and physicists specializing in the physics of the atmosphere. It may also be of interest to oceanographers concerned with the contamination of seas and oceans with radioactive waste products.

COVERAGE: This is a collection of 15 articles dealing with various problems of nuclear meteorology. The rapid development of the methods of radiometry opened the possibility of measuring minute particles of radioactive substances

Card 1/43

Problems in Nuclear Meteorology (Cont.)

SOV/6277

with a great degree of accuracy. This again made it possible to use radioactive isotopes in various fields of science, including meteorology. Tests of nuclear arms and the dispersion into the atmosphere of the waste of atomic industry necessitated a thorough investigation of the patterns of the spread of aerosols and gases, sometimes throughout almost the entire atmosphere. Such investigation is connected with the wide use of the newest methods and results of meteorology and the physics of the atmosphere in general. On the other hand, the distribution in the atmosphere of air masses, labeled with radioactive atoms, gives the meteorologists a new method for the study of atmospheric processes. The entire complex of problems related to the study of the distribution of radioactive impurities in the atmosphere and the use of radioactive atoms as labels in air masses or clouds has lately received the name of "nuclear meteorology" and is regarded as a branch of the physics of the atmosphere. The present collection contains some general articles, as well as articles reporting on the results of special investigations of certain problems of nuclear meteorology conducted in 1960-1961. It is divided in three sections, each dealing with a certain type of problem of nuclear meteorology. Bibliographic references are included at the end of individual articles.

AUTHOR: Sisigina, T. I.

TITLE: The vertical distribution of radon in the boundary layer of the atmosphere (0-300 m) in connection with changes in meteorological conditions

SOURCE: AN SSSR. Izv. Ser. geofiz., no. 3, 1964, 414-421

TOPIC TAGS: radon, radon distribution, vertical distribution, atmosphere, boundary layer, meteorology, turbulent mixing, temperature inversion

ABSTRACT: The author has described the results of measuring radon in the lower atmosphere, the measurements being conducted at high meteorological towers. Results show that the concentration of radon in the atmosphere above a given surface depends to a considerable extent on the conditions of emanation. For a region with steady dry weather, the radon concentration in the atmospheric layer nearest the ground is 2-3 times that for the same layer on rainy days (other conditions being the same), when the emanation of radon from the ground is retarded. The maximal vertical gradient of radon concentration is observed during the hour when temperature inversion develops. The value of the coefficient of turbulent mixing of the atmosphere

Card 1/2

ACCESSION NR: AP4030343

computed by vertical distribution of radon coincides, within reasonable limits, with the values determined by other methods for similar conditions. "In conclusion, the author considers it her pleasant duty to thank S. G. Malakhov for his valuable advice during examination of the manuscript. The author also thanks her co-workers in the meteorological groups, headed by G. B. Mashkova and F. Ya. Klinov, who gathered the meteorological data, and by G. V. Dmitriev, who made the synoptic analysis." Orig. art. has: 3 figures, 2 tables, and 2 formulas.

TITLE: Seismic effect of manmade explosions in quarries

SOURCE: Ref. zh. Geofizika, Abs. 8G103

REF SOURCE: Tr. V Sessii Uch. soveta po narodnokhoz. ispol'z. vzryva.
Frunze, Ilim, 1965, 318-328

TOPIC TAGS: seismologic instrument, oscillograph, vibration measurement,
tensometer, wave propagation/VBP vibrograph, BEGIK vibrograph

ABSTRACT: Results are presented of experimental and analytic investigations to determine the relationship of seismoeruptive wave parameters during blasting in quarries and in mines. VBP and BEGIK vibrographs, dynamic tensometers with an 800-mm base, displacement tensometric counters, and magnetoelectric oscilloscopes were used. Depending on the effect of the explosion on the rock mass, three zones are defined: the proximate zone (from 50 m to the area), the intermediate zone (50—500 m from the blasting area), and the distant zone (over 500 m from the

Card 1/2

UDC: 550.342

ACC NR: AR6035078

blasting point). Oscillograms of earth displacement velocities showed that destruction begins about 50 m sec after the explosion. In the destruction zone, particles of earth move in one direction until the moment of destruction. Beyond the destruction zone, a vibration process is observed and the waves separate as the distance increases. In each zone, the relationships of the earth displacement velocities are determined when explosions are instantaneous. Various factors influencing the magnitude of the tremors during explosions are established (wave propagation conditions, size of the charge, direction of the detonation). TITLE: Degree of cohesion of carbon black particles, its determination, and its effect on the properties of carbon black mixtures and vulcanizates

PERIODICAL: Referativnyy zhurnal. Khimiya, no. 4, 1962, 616, abstract 4P409 (Kaučuk a plast. hmoty, no. 10, 1959, 364 - 371)

TEXT: A method of the absorption of oil by carbon black was studied that is suitable for determining the degree of cohesion of carbon black particles. The factors affecting the final results of oil absorption measurements were studied. The method consists in the titration of a small weighed portion of carbon black by means of linseed oil. The amount (ml) of linseed oil absorbed by 100 g of carbon black was determined. The reproducibility of the method and the effect of various factors on the characteristic values of linseed oil and dibutyl phthalate (I) absorption were studied. The reproducibility was $\pm 3\%$ with the same laboratory worker and $\pm 10\%$ in different laboratories. The characteristic values for the ab-

In a 37-year-old man a mixed tumour of the heart was diagnosed before operation. It proved to be a fibrolipoleiomyoma, the myomatous part being most probably derived from blood vessels. The cystic portions of the tumour are regarded as lymphatics and structures resembling lymphangendotheliomata.

TITLE: Stabilized source for constant current coulometry

SOURCE: Chemicke listy, v. 59, no. 5, 1965, 604-607, and insert facing p. 608

TOPIC TAGS: titrimetry, chemical laboratory apparatus, microchemical analysis

Abstract: Coulometric titration at constant current are used in analysis conducted on large numbers of samples. There are however very few sources for the supply of suitable apparatus. The authors describe an apparatus of their own design; it has a range of 0.2 to 40 mA and it is suitable for analysis where a limited amount of the analyzed substance is available, or for microanalysis. It is suitable for concentrations of 0.05 to 3 microequiv/ml, in iodometric determination of small amounts of H₂S (2 to 50 micrograms), and in titanometric determination of iron (0.002%) in Ti salts. Orig. art. has 3 figures and 2 graphs.

TITLE: [Method for making permanent magnets] CZ Pat. No. PV 1453-65

SOURCE: Vynalezy, no. 5, 1966, 9

TOPIC TAGS: magnet, permanent magnet material, magnetic alloy

ABSTRACT: A method for making permanent magnets having a pole structure by the electric slag smelting of an alloy for permanent magnets is described. The chemical composition of the alloy is 5 to 10% Al, 10 to 27% Ni, 5 to 40% Co, 1 to 10% Cu, 0 to 10% Ti, 0 to 4% Zr, 0 to 4% Nb, 0 to 4% Ta, and a residue of Fe in the crystallizer. The distinguishing feature of the method is that in order to direct the growth of the crystal in the axial direction of the crystallizer, in the direction of magnetization, the current density in the electrode is controlled and kept in the 0.3 to 3.5 A/mm² range through the temperature regime of the electric slag process using slag of chemical composition 40 to 100% CaF₂, 0 to 50% Al₂O₃, 0 to 50% CaO, 0 to 10% SiO₂, 0 to 5% MgO, 0 to 5% TiO₂.

TITLE: Concentration of uranium ores

PERIODICAL: Bányászati Lapok, no. 4, 1960, 257-264

TEXT: The article deals with the concentration of uranium ores, describing the development and the different concentration methods used in the Western countries and in the USSR. The gradual exhaustion of hydrothermal uranium ore deposits made it necessary to increase the exploitation of conglomerates and sedimentary deposits with a uranium content of only 0.1-0.5%, and to develop and introduce new profitable ore concentration methods. Emphasis is laid on the fact that uranium cannot be regarded as a metal and has no importance as a material with secondary structure such as iron and copper, but that it is a source of energy. The following methods for preparing the uranium ore for metallurgical use are known: (1) physical concentration methods and (2) chemical or hydrometallurgical methods. The selective grinding, carried out wet or dry in rod or ball mills,

Card 1/8

H/013/60/000/004/001/001
D018/D105

Concentration of uranium ores

and used in physical concentration methods, was recently improved by flocculation chemicals used in sedimentation. The flotation method which produces basic material for hydrometallurgical concentration plants, can be used for treating sulfides and even carbonates prior to final concentration. Successful experiments were recently carried out with concentration of uranium carbonates. Due to these experiments it is expected that separation of uranium ores into ores with low carbonate content suitable for acid separation and into ores with high carbonate content suitable for the alkaline process will be possible. In the flotation of uranium ores fatty acids and salts with high valence are used as collecting reagents, since both the primary and secondary deposits of uranium belong to the group of oxide ores. These reagents have long-chain hydrocarbon radicals and chemically active electrophilic centers. The fatty acids can be used, most successfully, in processing silicate uranium ores. The unfavorable influence of the fine mud, which originates from the ore grinding and which contains uranium in large quantities, can be reduced by varicus emulsions

Card 2/8

H/013/60/000/004/001/001
E018/D105

Concentration of uranium ores

as in case of fatty acids or other reagents not easily soluble in water. At present experiments are being carried out on emulsifying flotation reagents with supersonic waves. The gravitational process can successfully be used in concentrating pegnatite ores. The heavy-suspension process and the magnetic method are also widely used. The most recent method is radiometric grading which is based on the natural radioactivity of the uranium ore. This method is especially successful for ores where the uranium is not equally dispersed but is concentrated in lumps. The suitability of the radiometric method for grading can be determined by the contrast test. For the test several tons of sample ore are graded and the uranium content of each piece in the different grading class determined by radiometric analysis. This analysis is carried out with small-size grains in quantities weighing 1/2-2 kg. The contrast curve of the uranium ore, as shown in Fig. 4 and 5, can be drawn from data received from calculations. On the basis of these graphs the suitability of the radiometric method and the main production indices, such as weight, metal yield, etc., can be determined. Experience showed that the radiometric method can be used for en-

Card 3/8

H/013/60/000/004/001/001
D018/D 105

Concentration of uranium ores

riching ore grains larger than 25-50 mm. Successful experiments were recently carried out by grading grains of varied size, by using a radiometer for the automatic registering of differences in the quantity of gamma rays of the grain resulting from different grain sizes. The uranium ore is separated by radiometric separators at, or near, the mines. Such an installation consists of a conveyor belt, several meters long and 0.5-1.0-m wide, moving at a speed of 0.2-0.5 m/sec, above or below which one or more scintillation counters shielded by a lead screen against background radiation, have been installed. Previously, instead of scintillation counters Geiger counters were used. The ore is separated by the electromagnetic or pneumatic mechanism operated through an electronic relay system. The sketch of a separator operated by one radiometer is shown in Fig. 8. Fig. 9 shows a separator operated by 3 radiometers. In the USSR and also in Western countries experiments are being conducted on the use of radioactivity in concentrating non-radioactive ores, such as coals. The method used in these experiments, which employs various radioactive isotopes, is based on measuring the intensity of the ab-

Card 4/8

H/013/60/000/004/001/001
D018/D105

Concentration of uranium ores

sorbed or reflected radioactive rays. The heat treatment method has been successfully used in the concentration of torbernitites. The ore containing 1% of U_3O_8 is heated at 700°C for 1 hour, then cooled in water and separated according to the size of grain, taking 1 mm as limiting value. It has been proved that the uranium content of finely-ground ore can be increased to 0.209% with a uranium yield of 90.5% and with waste containing 0.025% of uranium. According to the authors the above mentioned physical methods are only preliminary concentration methods. Concentrates suitable for metallurgical use have not yet been produced by any of the above processes. There are 10 figures and 8 tables.

Determination of composition of bauxite from Málta (Czechoslovakia). V. Šálek (Slovén), 1949, 87, 281, 289. *Ind. min.*, 1950, 3(1A).—The mineral corresponds in composition and microstructure to Okružný yellow bauxite. Thermal analysis indicates a strong endothermic reaction at 500–520° (corresponding with the presence of Al_2O_3 hydrate) and weak endothermic and exothermic reactions showing the presence of a small amount of kaolinite. Dehydration curves show that the main loss of water begins at 400°. Rational analysis (Kallauner Matějka method) of the crude and calcined bauxite shows that SiO_2 is present as flint, kaolinite, and anal. SiO_2 . Time curves were used to study the solubility of Al_2O_3 , Fe_2O_3 , and TiO_2 in 10% HCl at 100° over a period of 12 hr. Petrographic analysis shows that the main constituent of the bauxite is disperse with ~12% of kaolinite and other more readily sol. aluminum constituents. The $\text{Fe}(\text{O})\text{O}(\text{OH})$ content is low (7.38%). Its presence is indicated by an intense coloration at 600° which fades at higher temp. when Fe_2O_3 is converted into other Fe oxides. The TiO_2 content is normal.

Determination of the constituents of cement insoluble in hydrochloric acid. V. Simek. Stavivo, 27, 396 (1969); Brit. Ceram. Abstracts, 49 (9) 391a (1969).

Variations in the results obtained during the determination of the cement component insoluble in acid induced S. to undertake an investigation into the conditions of the determination. A short comparative discussion is given on the English, American German, and Czech methods. With the Czech method the influence of the duration of action of HCl and the influence of time of digestion with Na₂CO₃ solution was studied. Some practical suggestions on the process of determination are given.

677. Determining the proportion of cement clinker and slag in slag cements.
—V. Šimek (Stavivo, 29, 189, 1980). Slag cements are prepared by thorough mixing and grinding of portland cement clinker and blast-furnace slags in various portions. Czechoslovakian standards specify that "Iron portland cement" should contain >70% portland cement and <30% slag. Blast-furnace cement contains >20% portland cement and <80% slag. The reasons are given why it is impossible to determine the proportion of clinker and slag by ordinary chem. analysis. The microscopic method, heavy liquid separation, and the method based on the determination of S content are described and practical examples are given. (2 figs., 2 tables.)

SISKE, V.

1186. The composition and properties of the underlying clays of the lignite basin in Northern Bohemia.—V. Siske (*Stavivo*, 28, 269, 1950). Up to the present the overlying clays have been investigated more thoroughly than the under-clays because, once the latter were reached, no further coal beds were expected and no great interest was shown. The main types and characteristics of under-clays are described and various theories of their origin put forward. A sample, which the author tested, is described. Microscopical, mechanical, thermal and chem. analyses were performed. The first two yielded no informative results, owing to the special properties of the clay. D.T.A. showed that the main components were probably hydargillite (gibbsite) and kaolinite. The chem. analysis gave the following results (%): SiO₂, 35.53; Al₂O₃, 50.54; Fe₂O₃, 1.84; TiO₂, 10.65; P₂O₅, 0.79; V₂O₅, 0.24; CaO, 0.35. On the basis of the thermal and chemical analyses the mineralogical comp. was calculated as follows (%): Al₂O₃.2SiO₂.2H₂O, 61.20; Al(OH)₃, 25.18; TiO(OH)₂, 10.47; Fe₂O₃(OH)₂, 2.15; organic matter, 2.03; Ca₃(PO₄)₂, 0.52; AlPO₄, 0.39. Tests for refractoriness, firing colour, and solubility of Al₂O₃ and TiO₂ in various concns. of NaCl and H₂SO₄ were made. The refractoriness is high, the shrinkage is also very high. On the basis of these preliminary investigations it is suggested that the clay should be used in the manufacture of grog and with addition of Al₂O₃ in the manufacture of technical mullite for use when a high proportion of TiO₂ does not matter and where the refractories are not subjected to too high a pressure. When the clay is correctly calcined, almost the whole of the Al can be dissolved by H₂SO₄; Ti is almost insol. in dil. H₂SO₄, but is sol. in conc. H₂SO₄. (3 figs., 6 tables.)

Accelerated differential thermal analysis. Cyril Gal-
parin, Ivo Proks, and Vladimír Šilík (Tech. Univ., Bratis-
lava, Czech.). *Silikaty* 3, No. 1, 64-73 (1959).—Equipment
described earlier (*C.A.* 52, 114782, 126748) is used to
register DTA curves from magnesite, limestone, dolomite,
gypsum, and siderite. An increase in the rate of heating
increases the temp. difference between standard and sample.
The temp. intervals between the peaks on the DTA curve
also increase. Therefore, it is possible (at this accelerated
DTA) to use samples ≤ 0.03 g. This is advantageous since
the amt. of gaseous products produced by the heterogeneous,
reversible reactions which occur is so small that it cannot
affect further phases of the 'decompn.' or other reactions
which occur at higher temp. The temp. interval between
the peaks also increases with the fineness of the samples.
If the correct conditions are chosen, the curves of the
accelerated DTA will coincide more or less with the ordinary
DTA curves.

TITLE: Method of calculating the heat evolved in diesel engines by means of indicator diagrams

SOURCE: Constructia de masini, no. 10, 1964, 534-537

TOPIC TAGS: diesel engine, heat of combustion, combustion engineering

ABSTRACT: A theoretical derivation of a formula for determining the heat released in Diesel engines. The formula makes use of the indicator diagram of the engine and takes into account the quantitative and qualitative variations in the combustion mixture. Orig. Art. Incl.: 38 formulas and 1 tables.
