TITLE: A precision transistorized pulse-time multiplication and division unit

SOURCE: Avtomatika i telemekhanika, v. 26, no. 10, 1965, 1818-1823

TOPIC TAGS: computer component, arithmetic unit, computer circuit, analog system,  
transistorized circuit 160, 44

ABSTRACT: The authors describe a four-quadrant multiplier and divider based on the widely known principle of pulse-time multiplication. A block diagram of the device is shown and its operation is explained. The device has a maximum relative error of 0.1% in an ambient temperature range from 0 to +60°C. A schematic diagram is given for the electronic part of the device together with a detailed description of its operation. The circuit of the device is divided into two sections. The first section contains a sawtooth voltage generator, common collector amplifier, Schmitt trigger circuit, and two pulsed voltage dividers. The operation of the voltage dividers is illustrated by time diagrams. This first section is used for pdm and pam of the square-wave voltage. The second section of the multiplier-divider is a d-c amplifier. This unit has a voltage amplification factor of 20,000, input impedance of 5 KΩ, and a maximum zero drift at the output of 0.4 mv from +20 to +60°C. Data are given on error

TITLE: One possibility for construction of digital analog functional converters

SOURCE: Avtometriya, no. 2, 1966, 90-98

TOPIC TAGS: digital analog converter, circuit design, mathematic analysis

ABSTRACT: A method is described for the construction of digital-analog functional converters based on preliminary expansion of the function into a series by Walsh functions. It is shown that the elements of the digital-analog converter are interpreted easily by the category of this expansion. Examples are presented of the realization of some digital-analog functional converters. The limitations within which the application of this method will give a gain in comparison with known methods are determined. The advantages of converters constructed using Walsh function expansion are simplicity of the analog portion of the circuit and the constant output impedance of the analog portion of the circuit, which allows them to be used with any load without disrupting the nature of the dependence reproduced. Orig. art. has:

AUTHOR: Smolov, V. B.; Balashov, Ye. P.

TITLE: Electronic computer for acoustic core sampling

160

SOURCE: IVUZ. Priborostroyeniye, v. 8, no. 2, 1965, 80-85

TOPIC TAGS: geological surveying, computer design, digital analog computer, mine core sampling, acoustic core sampling, seismic sampling

ABSTRACT: In the development of automatic equipment for acoustic core sampling in mine shafts, the basic output parameter of which is the velocity of propagation of elastic oscillations with depth  $V_{\text{form}}$ , it is also advisable to have a computer unit for the automatic computation of the sum transit time  $t_g$  of the elastic oscillations in depth. The presence of the second yield parameter  $t_g$  permits a matching of the data of acoustic core sampling with information derived from seismo-sampling, thus providing a more complete picture of the geological section under study. The problems involved in the determination of the sum transit time  $t_g$  are discussed, and it is pointed out that the difficulties of designing highly stable and sufficiently accurate electronic (vacuum-tube and semiconductor) DC

Card 1/3

L 44773-65

ACCESSION NR: AP5011738

differentiating and integrating amplifiers and electronic dividers operating in a broad voltage range are such as to make it impossible to solve this problem with an error on the order of several percentage points of  $(t_g)_{\max}$  and that, consequently, despite high operating speed, an electronic version using continuous-action devices seems hardly feasible. A variety of reasons point to the advisability of employing digital-analog computers to provide  $V_{form}$  and  $t_g$  in the form of continuously changing voltages of direct or alternating current. In this article, the authors describe a digital-analog computer for geological survey operations, designed by the Kafedra schetno-reshayushchey tekhniki LETI im. V. I. Ul'yanova (Department of Computer Engineering of the Leningrad Institute of Electrical Engineering) jointly with the Leningradskiy filial NII geofiziki (Leningrad Branch of the Scientific Research Institute of Geophysics) in 1958. The purpose of the device is to calculate the velocity of propagation, and it is based on a method of digital integration according to Euler's formula. Largely transistorized, tests have shown that this type of computer may be considered optimal for the specific purposes for which it was designed. A detailed diagram of this sum transit time computer is given in the article and explained, together

Card 2/3

L 44773-65

ACCESSION NR: AP5011738

with a schematic representation of the input circuitry of the device. The computer has provided a stable accuracy in the determination of  $t_g$  not worse than 0.5% of  $(t_g)_{\max}$ . Weighing 1.5 kg and measuring 600 X 350 X 100 mm, the device draws only 6 watts. Orig. art. has: 3 figures and 4 formulas.

TITLE: Quantitative determination of monomeric unsaturated carboxylic acids by the titration method in nonaqueous solutions

PERIODICAL: Plasticheskiye massy, no. 6, 1962, 51-53

TEXT: A simple and quick method has been developed for the quantitative determination of individual monomeric and dibasic unsaturated acids (maleic and fumaric acid) and their mixtures. They are potentiometrically titrated in isopropyl alcohol by means of 0.1 N benzene-methanol solution of tetramethyl ammonium hydroxide. ~0.3 mg-equiv. acid in isopropyl alcohol was mixed with 40 ml isopropyl alcohol, the electrodes inserted, stirred, and mixed with tetramethyl ammonium. The following monobasic unsaturated acids were titrated: crotonic, undecylenic, oleic, elaidic, erucic, sorbic, and linoleic acids. The acids insoluble in water with the exception of crotonic acid corresponded to the acidity of crotonic acid ( $2.04 \cdot 10^{-5}$ ). The error of the

Card 1/3

Quantitative determination of...

S/191/62/000/006/011/016  
B110/B138

quantitative determination is  $\leq 1\%$ . In addition, the following dibasic unsaturated acids were titrated: maleic, fumaric, itaconic, and citraconic acids. In isopropyl alcohol, each carboxyl group of dibasic acids is titrated individually, which is characterized by two breaks in the titration curves. The relative error in the quantitative determination of dibasic unsaturated acids is  $\leq 1\%$ . In isopropyl alcohol, the determination of mixtures of both dibasic acids alone, and of dibasic with monobasic acids is possible. Three breaks in the titration curve were found when a mixture of maleic and fumaric acid was titrated. The first break corresponds to the first step of neutralization of maleic acid, the second to the complete neutralization of fumaric acid, and the third to the second step of neutralization of maleic acid. Maleic acid was titrated with  $V_m = 2(V_3 - V_2)$ . The volume used for the neutralization of fumaric acid is determined from  $V_F = V_3 - 2(V_3 - V_2)$ . When maleic and itaconic acid are mixed, the first break corresponds to the first step of neutralization of maleic acid, the second to the first step of neutralization of itaconic acid, and the third to the combined neutralization of the second carboxyl groups of both acids. For the

Card 2/3

Quantitative determination of...

S/191/62/000/006/011/016  
B110/B138

neutralization of itaconic acid,  $V_{It} = 2(V_2 - V_1)$  was used, and for the neutralization of maleic acid,  $V_M = V_3 - 2(V_2 - V_1)$ . For mixtures of dibasic and monobasic acids, the neutralization of dibasic acid requires  $V = 2(V_3 - V_2)$ , and the neutralization of monobasic acid,  $V = V_3 - 2(V_3 - V_2)$ . The relative error of the quantitative analysis is here  $\leq 2\%$ . There are 3 figures and 2 tables.

TITLE: On the Solution of the Equations of the Spatial Theory of Elasticity by Means of Three Maxwell Stress Functions (O reshenii uravneniy prostranstvennoy teorii uprugosti pri pomoshchi trekh funktsiy napryazheniy Maksvella)

PERIODICAL: V sb.: Tr. nauch. konferentsii Stalinskogo ped. in-ta. Nr 1. Kemerovsk. kn. izd-vo, 1956, pp 296-301

ABSTRACT: The equations of static equilibrium and the Beltrami relationships are satisfied if the stresses are expressed by three biharmonic Maxwell stress functions. The author, however, fails to note that the stress functions so introduced are not independent; therefore, sections 2 and 3 of the paper under review are erroneous. For example, a comparison of expression (2.3) and formulae (1.6) would lead to the (erroneous) conclusion that the deflections in a spatial problem of the theory of elasticity do not depend upon Poisson's number.

PERIODICAL: Nauchnyye doklady vysshey shkoly. Fiziko-matematicheskiye nauki, 1958, Nr 4, pp 119 - 122 (USSR)

ABSTRACT: The author considers the deformation of a solid or hollow circular cylinder ( $R_1 \leq r \leq R$ ,  $-1 \leq z \leq 1$ ) for arbitrary stress symmetric to  $z = 0$  of the surface. The boundary conditions on the front walls are satisfied in the sense of Saint-Venant. For the displacements the author uses the Galerkin solutions in cylindrical coordinates. Only the case of a simple bending under influence of normal stress is calculated in detail. There is 1 Soviet reference.

TITLE: Equipment and method for impact compacting of metal chips

SOURCE: Kuznechno-shtampovochnoye proizvodstvo, no. 9, 1964, 30-33

TOPIC TAGS: chip compacting, explosive chip compacting, explosive forming, high energy rate forming, HERF

ABSTRACT: The Khar'kovskiy aviationsionnyy institut (Khar'kov Aviation Institute) has developed a method and designed an experimental unit for explosive compacting of metal chips. The unit, a kind of horizontal hammer (see Fig. 1 of the Enclosure), operates as follows: A portion of chips 4 is charged into the container 5 rigidly connected to the rear plate 8. The explosive charge, or a mixture of gas and air, is fed into the explosion chamber 1. When the charge is exploded, the hot explosion products propel the projectile 3 along the barrel 2 and into the container 5. At the same time the barrel moves under the effect of the explosion and pulls the container in the opposite direction through connecting rods. This increases the force with which the

Card 1/3

L 8741-65

ACCESSION NR: AP4045811

projectile hits the chip charge. The compacted chips are ejected and the projectile is returned to the barrel by the hydraulic cylinder 10. With a combustion-chamber volume of 17.5 l, the unit produces an impact with an energy of 18,000 m·kg, which is sufficient to compact 10—14 kg of chips to a density of 4.5—5.5 g/cm<sup>3</sup>. The density could be increased to 6.0—6.5 g/cm<sup>3</sup> by preheating the chips to 400—450°C, which also eliminates the oil sticking to the chips. The unit capacity is 200 kg/hr. A special advantage of the unit is that all the energy is absorbed within the system; no heavy foundation is needed. Orig. art. has: 5 figures.

TITLE: A Mechanism for Feeding Metal in Rolls of a Rolling Mill  
(Mekhanizm dlya zadachi metalla v valki prokatnogo stana)

PERIODICAL: Stal', 1959, Nr 5, pp 441 - 443 (USSR)

ABSTRACT: A mechanism for feeding metal into rolls (proposed by E.D. Smolovikov) operating on a three-high mill rolling strip for the manufacture of tubes is described and illustrated (Figures 1,2). The use of the forced feeding of the mill increased its output by 5%.  
There are 2 figures.

TITLE:

A strobophotographic method of determining the calibrated velocities of flow of fluids

PERIODICAL: Technika lotnicza, no. 1, 1962, 21

TEXT: Polish patent no. 40055, Class 42 o, 19, July 10, 1957; an extension to patent no. 55903 by the same inventor. Into a stream of fluid a solid, spherical and luminous body is introduced, its weight being low, so that it may acquire the velocity of the stream in a short time and distance. The indicating body is illuminated with a flashing light of known frequency and photographed on a single plate to allow an estimation of the velocity. In another version of the patent, the indicating body is allowed to fall freely in a stationary fluid. When the forces of gravity and resistance become equal the limiting velocity of the body is estimated as before. Knowing this limiting velocity the body can be introduced into a stream of fluid moving vertically upwards and the flow regu-

TITLE: Lev Gerasimovich Loytsyantskiy. On His 60th Birthday and His 40th Year of Scientific and Pedagogical Activity

PERIODICAL: Inzhenerno-fizicheskiy zhurnal, 1961, Vol. 4, No. 2,  
pp. 116-118

TEXT: Professor L. G. Loytsyantskiy, Doctor of Physical and Mathematical Sciences, Stalin Prize winner, is an authority in the field of the boundary layer theory. Since 1922 he has been working at the Institut im. M. I. Kalinina (Institute imeni M. I. Kalinina) and was appointed professor in 1928. The Kafedra aerogidrodinamiki (Department of Aero-hydrodynamics) created by him in 1934 has a very successful activity on record and under his guidance has developed novel methods of calculating the boundary layer of compressible and incompressible liquids. Some special fields of aerohydrodynamics with which L. G. Loytsyantskiy has been concerned are enumerated and his merits are pointed out. Special

mention is made of his contribution to the construction of the Dneproges (Dnepr Hydroelectric Power Plant), Volzhskiy kaskad (Volga Cascade), and Bratskaya gidrostantsiya (Bratsk Hydroelectric Power Plant). His best known pupils are G. N. Krushilin, Corresponding Member of the AS USSR, Professor E. L. Blckh, I. L. Povkh, and others. In cooperation with A. I. Luriya he has published a textbook on theoretical mechanics and a number of monographs. In the years of World War II he developed partly alone and partly in cooperation with Academicians N. Ye. Kochin and A. A. Dorodnitsyn at the Tsentral'nyy aerogidrodinamicheskiy institut im. N. Ye. Zhukovskogo (Central Institute of Aerohydrodynamics imeni N. Ye. Zhukovskogo) several technical calculation methods of the boundary layer of variously shaped bodies. The importance of several publications on the mechanics of viscous liquids and gases, on the boundary layer theory, on the jet theory, etc., is pointed out, and next, the idea put forth by him in 1933 regarding the "internal similarity" of the turbulent transport mechanism is discussed. This idea made it possible to take account of the effect of viscosity upon the friction and the heat exchange in arbitrary

TITLE: Mechanism of heat and mass transfer with sublimation of substances in a rarefied medium

PERIODICAL: Inzhenerno-fizicheskiy zhurnal, v. 5, no. 11, 1962, 41 - 47

TEXT: In a previous paper (P. A. Novikov, IFZh, no. 10, 1961) a study was made of heat and mass transfer in the sublimation of naphthalene under static conditions (0.07 mm Hg up to atmospheric pressure) and with either free or forced convection. The data resulting from these studies are analyzed in detail. Four different transfer mechanisms are distinguished as functions of pressure: (1) in the range of atmospheric pressure down to 40 mm Hg the sublimation intensity is weak, the substance is transferred by molecular diffusion and convection. The experimental results for free convection can be well described by  $Nu = 0.373 Gr^{0.33}$  and  $Nu' = 2.5 Gr^{0.36}$ ; for the case of forced convection  $Nu = 2.7 \cdot 10^{-3} ReGu^{0.17} + 0.1 Gu^{-0.59}$  and  $Nu' = 1.3^{56} \cdot 10^{-1} ReGu^{0.57} + 1.4 \cdot 10^{-1} Gu^{-0.73}$ . (2) Between 40 and 0.1 mm Hg

S/170/62/005/011/002/008  
B104/B102

Mechanism of heat and mass ...

the sublimation intensity rapidly increases as pressure decreases. At 0.5 - 1 mm Hg it attains a maximum. Heat and mass transfer are characterized by a special type of mass exchange, the hydrodynamics of which depends on the pressure and the rate at which the state of aggregation of the substance changes. With free convection  $Re^* = AGu^n(\Delta p/p)^m \exp(-k\Delta p/p)$ , with forced convection  $Re^* = BGu^a(\Delta p/p)(w/v_a)^c \exp(-d\Delta p/p)$ . (3) In the pressure range between 0.1 and 0.07 mm Hg the transfer is characterized by molecular-viscous conditions where the discrete structure of the substance becomes manifest. In a layer on the solid substance whose thickness corresponds to the mean free path, the mass is exclusively transferred by molecular processes. With Knudsen numbers of  $Kn > 0.04$  the gas velocity has no effect on the intensity of heat and mass transfer. For free convection  $Nu = 5.96 \cdot 10^{-4} Gu^{-5.23} Kn^{2.78}$  and  $Nu' = 3.61 \cdot 10^{-2} Gu^{-1.86} Kn^{1.02}$ . (4) The fourth variety of heat and mass transfer is a process of free molecules in which the motion of the molecules toward a solid substance is not disturbed by collisions with molecules emitted from the surface of the solid.

TITLE: Heat and mass transfer in a boundary layer on a porous wall

SOURCE: AN BSSR. Institut teplo- i massoobmena. Teplo- i massoobmen  
tel s okruzhayushchey gazovoy sredoy (Heat and mass exchange of  
bodies with the surrounding gaseous medium). Minsk, Nauka i Tekhnika,  
1965, 70-85

TOPIC TAGS: boundary layer theory, heat transfer, mass transfer,  
turbulent boundary layer, vaporization, surface property

ABSTRACT: The article considers the thermodynamic and hydromechanical  
characteristics of the process of evaporation of a drop-form liquid  
from a porous wall. The experimental sample (illustrated in a  
figure) was a glass with a diameter of 0.054 meters and a length of  
0.25 meters, equipped with an ice calorimeter insulated from the  
rest of the internal space. The experiments were carried out in an  
aerodynamic tube with a sealed working section. The velocity of the

Card 1/3

L 8927-66

ACC NR: AT5027195

air flow could be varied smoothly from 2 to 18 meters/sec, and the temperature of the flow was measured from 15 to 150°C. The experimental conditions were the following: flow temperature--70, 100, 130°C; moisture content of the medium and  $\varphi$ --4.1 and 0.5%, respectively; flow velocity--6, 10, 12, and 15 meters/sec. The range of Reynolds numbers, consequently, was  $(2-7) \times 10^4$ . The generalized relationship found for the whole range of experimental parameters for the front end of the surface of the cylinder had the form:

$$Nu_x = 1.48(e^{-2.4x} + 0.2e^{-5.5x}) \sqrt{Re_x K^{0.28}} \quad (2)$$

The coefficients and the power exponents in the above formula were found by the method of least squares. The article proceeds to consider the question of developed turbulent flow in the boundary layer. The experiments on heat and mass transfer were carried out on the evaporation of water in a turbulent boundary layer from a flat ceramic fireclay plate, in a flow of heated air with a gradient. The velocity of the air flow in the working column of the aerodynamic tube was varied from 2 to 50 meters/sec. The experimental body was a single porous plate, mounted in a box divided into 8 subchambers by partitions. Measurements were made of the velocity and the temperature of the flow, the degree of its turbulence under each set of

Card 2/3

ACC NR: AT5027195

temperature and velocity conditions, and the temperatures of the surface of the plate (at 16 points), the side walls of the box, the water in each chamber, and the walls of the working column. In this case, the following relationship was established:

$$\overline{Nu}_q = 0.036 Re^{0.8} (1 - b_r)^2; \quad \overline{Nu}_m = 0.03 Re^{0.8} (1 - b_r)^{3.1} \quad (5)$$

TITLE: The mechanism of heat and mass transfer with vibration of a subliming body under conditions of free convection in a rarefied gaseous medium

SOURCE: AN BSSR. Institut teplo- i masoobmene. Voprosy nestatsionarnogo perenosa tepla i massy (Problems of nonstationary heat and mass transfer). Minsk, Nauka i tekhnika, 1965, 105-111

TOPIC TAGS: heat transfer, mass transfer, convective heat transfer, vibration effect

ABSTRACT: The experiments described in the article were carried out under steady state conditions with free convection. The total pressure of the surrounding medium was varied within wide limits from 745 to 0.1 mm Hg. A figure shows the dependence of the heat transfer rate on the vibration rate of the subliming body for different pressures of the surrounding medium. The figure represents a plot of the Nusselt number (Nu) against the vibrational Reynolds number ( $Re_{\tilde{v}}$ ). At total pressures

69  
B+1

Card 1/3

L 12116-66

ACC NR. AT6001768

of the surrounding medium from atmospheric to 50 mm Hg, the sections of the  $Nu f(Re_v)$  curves for values of  $Re_v$  above the critical value lie parallel to each other. This means that, in this pressure interval at small sublimation rates, mass transfer does not exert any considerable effect on transfer of matter in the boundary layer. With a decrease in the total pressure below 50 mm Hg, the angle of the slope of the curves to the abscissa decreases, approaching zero at a pressure of 0.1 mm Hg. At this pressure of the surrounding medium, the heat transfer rate no longer depends on the rate of vibration of the body. At values of the vibrational Reynolds number below the critical, the Nusselt number practically does not depend on the Reynolds number. With an increase in the vibrational Reynolds number above the critical value, the heat transfer rate increases sharply. With a decrease in the average rate of vibration of the body below the critical value, the heat transfer rate approaches that for conditions of free convection. The results also indicate that the rate of heat and mass transfer processes accompanied by vibration depends also on the direction of the vibrations with respect to the direction of movement of the gas. If the vibrating surface is perpendicular to the direction of movement of the gas, the boundary layer may be destroyed, which leads to an increase in heat and mass transfer rates. If the direction of the vibration coincides with the direction of the movement of the gas flow, the boundary layer may not be

O

destroyed but merely reduced in thickness; in this case such a strong increase in the heat and mass transfer rates will not follow, Orig. art. has: 3 figures.

teplo- i massoobmena AN BSSR)

TITLE: Investigation of the distribution of the temperature field  
between parallel walls during sublimation under vacuum conditions

SOURCE: AN BSSR. Institut teplo- i massoobmena. Teplo- i massoobmen  
tel s okruzhayushchey gazovoy sredoy (Heat and mass exchange of  
bodies with the surrounding gaseous medium). Minsk, Nauka i Tekhnika,  
1965, 118-122

TOPIC TAGS: heat transfer, temperature distribution, sublimation

ABSTRACT: The temperature field was investigated for three cases of  
heat and mass transfer: 1) horizontal arrangement of plates (upper  
position of the heating plate); 2) horizontal arrangement of the  
plates (lower position of the heating plate); and 3) vertical  
arrangement of the plates. A figure, based on experimental data,  
shows the distribution of the temperature between parallel plates for  
"pure" heat transfer, at total pressures of the surrounding medium

Card 1/3

L 8837-66

ACC NR: AT5027197

from 30.6 to 533 newtons/m<sup>2</sup>. The distance from the heating surface, y, was 0.02 meters between plates. When the surface temperature of the heating plate was 320°K, the thickness of the thermal boundary layer was 0.015 meters. With an increase in the temperature of the heating surface to 337°K, sigma increased to approximately 0.017 meters. With a further increase in temperature up to 360 and 373°K, the thickness of the thermal boundary layer bridges over the distance between the plates, and exceeds a value of 0.02 meters. Thus, in the given pressure interval, the thickness of the thermal boundary layer is a function only of the temperature of the heating surface. Another figure, also based on experimental data, shows the temperature distribution between parallel plates when a phase transformation (sublimation) is taking place on the surface of one of the plates. The subliming material was ice (H<sub>2</sub>O). The total pressure of the surrounding medium was 30.6 newtons/m<sup>2</sup>. The subliming plate was at a distance of 0.02 meters from the heating plate. The temperature of the heating surface was varied from 315 to 363°K. Analysis of the curves shows that with sublimation of a substance under vacuum conditions, the curves for the temperature change between the objects being investigated obeys a more complicated relationship than in the case of "pure" heat transfer. Orig. art. has: 3 figures.

TOPIC TAGS: surface active agent, heat transfer, Reynolds number,  
FRICITION, FLUID FLOW, HYDRODYNAMICS, LUBRICATION

ABSTRACT: A determination was made of the hydrodynamic friction resis-  
tance in the flow of a fluid in tubes. The surface of the tubes was  
carefully cleaned to avoid the presence of adsorbed films of foreign ma-  
terial. On the basis of experimental data obtained on the flow time of  
the fluid, determinations were made of the friction coefficients of tubes  
made of various materials. The walls of the tubes were rubbed previous-  
ly with distilled water and with various surface active agents. The  
effect of the surface active agents appears gradually and reaches a max-  
imum after a period of from 1 to 10 minutes, after which it remains con-
