TITLE:

The problem of estimating the magnetic and the gravitational

anomalies of three-dimensional bodies

PERIODICAL: Razvedka i okhrana nedr, no. 12, 1960, 28 - 32

TEXT: In order to simplify the calculation of three-dimensional anomalous fields, a method is proposed (based on the idea of S. V. Shalayev) to reduce the three-dimensional fields to two-dimensional ones. By introducing into Laplace's equation for three-dimensional bodies a new function

$$U_1 = \int_{-\infty}^{+\infty} U(x, y, z) dy = U(x, z)$$
 (2)

the equation is written as follows:

$$\triangle U_1 = \frac{\lambda^2 U_1}{\partial x^2} + \frac{\partial^2 U_1}{\partial y^2} + \frac{\lambda^2 U_1}{\partial z^2}$$
(3)

as Card 1/9

$$\frac{9 \lambda_5}{9 50^1} = 0$$

(4)

21345 8/132/60/000/012/002/004 A054/A130

The problem of ...

it follows that

$$\frac{\partial^2 U_1}{\partial x^2} + \frac{\partial^2 U_1}{\partial z^2} = 0 \tag{5}$$

Formula (5) corresponds with Laplace's equation for two-dimensional problems. With the aid of function (2) the reduction of three-dimensional anomalies to two-dimensional ones in the case of the pointed pole is obtained as follows: the formula of the vertical component of the magnetic field, Z, is

$$Z = \frac{mh}{(x^2 + y^2 + h^2)^{3/2}}$$
 (6)

(m = magnetic mass, h = the depth of location of the pole). When integrating (6) according to (2) we obtain:

$$Z_{1} = \int_{-\infty}^{+\infty} \frac{mh}{(x^{2} + y^{2} + h^{2})^{3/2}} dy = \frac{2mh}{x^{2} + h^{2}},$$
 (7)

This equation is in agreement with the formula of the vertical component Z for the line of poles, while the numerical value of h remains the same as for pointed Card 2/9

21.3145 \$/132/60/000/012/002/00¹4 1.05¹4/A130

The problem of ...

poles. The reducing method for spherical beds is:

$$Z = \frac{M(2h^2 - x^2 - y^2)}{(x^2 + y^2 + h^2)^{5/2}}$$
 (8)

(M = magnetic moment, h = the depth of the centre of the sperical bed). By integrating (8) according to (2), we obtain:

$$Z_1 = \int_{-\infty}^{+\infty} \frac{M (2h^2 - x^2 - y^2)}{(x^2 + y^2 + h^2)^{5/2}} dy = \frac{2M (h^2 - x^2)}{(x^2 + h^2)^{1/2}}$$
(9)

The equation corresponds with the formula of the vertical component Z for a horizontal cylinder, with the same parameter h as for a spherical bed. The reducing method for a vertical prism sunk to infinite depth is as follows: the formula of the vertical component of the magnetic field Z is:

Card 3/9

21345

\$\\/132\/60\/000\/012\/002\/00^{\\\}4 \\\05^{\\\}4\/130

The problem of ...

$$Z = \sigma \left[\arctan \frac{x+b}{h} \cdot \frac{l+y}{\sqrt{(x+b)^2 + (y+l)^2 + h^2}} - \arctan \frac{x+b}{h} \cdot \frac{l-y}{\sqrt{(x+b)^2 + (l-y)^2 + h^2}} - \arctan \frac{x-b}{h} \times \frac{l+y}{\sqrt{(x-b)^2 + (y+l)^2 + h^2}} + \arctan \frac{x-b}{h} \cdot \frac{l-y}{\sqrt{(x-b)^2 + (l-y)^2 + h^2}} \right], (10)$$

(6 = magnetic density, 2b = the width of the prism at axis x, 2l = the length of the prism at axis y, h = the depth to the upper edge of the prism). By integrating (10) according to y within infinite limits, we obtain the formula of the vertical component Z for a vertical layer with the same 2b, h parameters as for prism y:

Card 4/9

21345

8/132/60/000/012/002/004 A054/A130

The problem of ...

$$Z_{1} = \sigma \int_{-\infty}^{+\infty} \left[\operatorname{arctg} \frac{x+b}{h} \frac{l+y}{v(x+b)^{3} + (l+y)^{3} + h^{3}} - \operatorname{arctg} \frac{x+b}{h} \frac{l-y}{\sqrt{(x+b)^{3} + (l-y) + h^{2}}} - \operatorname{arctg} \frac{x-b}{h} \frac{l+y}{\sqrt{(x-b)^{3} + (y+l)^{3} + h^{3}}} + \operatorname{arctg} \frac{x-b}{h} \frac{l-y}{\sqrt{(x-b)^{3} + (l-y)^{3} + h^{3}}} \right] dy = 2\sigma \left[\operatorname{arctg} \frac{x+b}{h} - \operatorname{arctg} \frac{x-b}{h} \right].$$

When calculating (2), we use the formula of the parallelogram:

$$U_1 = \Delta y \sum_{n=1}^{\infty} U_1 \tag{12}$$

 $(\Delta y = constant distance between the points along the line of parallel axis y; n = number of points selected for calculation; U = potential function, cor-Card 5/9$

21345 S/132/60/000/012/002/004 A054/A130

The problem of ...

responding with H, Z, H_X , Z_X , $\triangle g$, U_A , U_{XZ} (Abstracter's note: g = V), U_{AX} , U_{XZX} . Formula (12) can be made more convenient for calculations. The distance $\triangle y$ between points having a U_1 value can be expressed by the length of the interval of integration according to

 $\Delta y = \frac{2L}{n} (13)$

(2L = the length of the integration interval according to axis y). Substituting the above value for Δy in (12) we obtain:

 $U_1 = \Delta y \sum_{l=1}^{n} U_l = \frac{2L}{n} \sum_{l=1}^{n} U_l = 2LU_{cp},$ (14) где $U_{cp} = \frac{\Sigma U_l}{n}$.

Where $U_{aver} = \frac{\sum U_1}{n}$

(Abstracter's note: subscript cp has been changed into aver [average]). In practice the integration method is as follows: the field of anomalies will be covered by a system of parallel profiles arranged perpendicularly to axis y, and at a distance of Δ y from each other. The curve U is plotted for each profile. Next, all the profiles are combined into one and from the corresponding curves of

Card 6/9

21345

S/132/60/000/012/002/00¹4 A05¹4/A130

The problem of

three-dimensional anomalies an average curve is plotted, which corresponds with a two-dimensional body having a section equal to the projection of the three-dimensional body on the x, o, z surface. Depending on the mutual location of the surveying profiles in relation to the strike of anomaly, there are several possibilities: 1) the profiles intersect the anomaly perpendicularly to the strike and are parallel. In this instance integration gives a curve for defining the elements of the bedding of the body in cross section which is perpendicular to the strike of the anomaly; 2) the surveying profiles intersect the anomaly in the strike direction and are parallel. In this case a curve is obtained for defining the elements of the bedding of the body in cross section, parallel to the strike of the anomaly; 3) the surveying profiles intersect the anomaly at a certain angle to the strike direction and are parallel; 4) the surveying profiles intersecting the anomaly are not parallel. (2) would have to be integrated within infinite limits, which is practically impossible, however, the error arising when integrating with finite instead of infinite limits must be corrected. relative error for the pointed pole is corrected by the following formula:

 $\frac{\Delta Z}{Z} = 1 - \frac{L/h}{\sqrt{1 + (L/h)^2}}$ (15)

Card 7/9

X

21345

The problem of....

S/132/60/000/012/002/004 A054/A130

(2L = the length of the profile of integration on axis x). The correction for a spherical bed is carried out by the following formula:

$$\frac{\Delta Z}{Z} = 1 - \left[\frac{2 (L/h)}{\sqrt{(L/h)^2 + 1}} \right] - \frac{(L/h)^3}{\sqrt{(L/h)^3 + 1}}$$
(16)

The relative error for a vertical prism $L/h = \frac{1}{4}$ does not exceed this value either. The method recommended has been confirmed by calculations and by reference to graphs for the three mentioned cases. There are 2 figures.

TITLE:

On the problem of interpreting magnetic and gravitational anomalies

of three-dimensional bodies

PERIODICAL: Referativnyy zhurnal.Geofizika, no.7, 1961, 23-24, abstract 7A2O5

("Razvedka i okhrana nedr", 1960, no. 12, 28 - 32)

TEXT: To simplify calculations, a method is proposed of reducing threedimensional field anomalies to two-dimensional ones. The method consists in the integration of any harmonic function along one of the coordinate axes, e.g. y, yielding a new function, which satisfies the Laplace equation on a plane (xz), The numerical integration of the anomalous field is performed and, as a result, an anomaly is obtained corresponding to a two-dimensional body having the same parameters in the plane (xz) as the unknown body. The method is applicable to individual magnetic and gravitational anomalies.

Investigation of Acridine Derivatives (Izucheniye proizvodnykh akridina) I. Synthesis of 1-Nitro-2-Methoxy-9-Chloroacridine

(I.Sintez 1-nitro-2-metoksi-9-khlorakridina)

PERIODICAL:

Zhurnal obshchey khimii, 1958, Vol. 28, Nr 8,

pp. 2207 - 2213 (USSR)

ABSTRACT:

In spite of their technical significance, many theoretically possible acridine derivatives have hitherto escaped notice. Their synthesis could furnish general rules regarding the dependence of various properties of the acridine compounds on their ___ structure. The authors were interested in the synthesis of undescribed nitro-methoxy derivatives of acridine having both substituents in the orthoposition. A possible way of the synthesis of such acridine derivatives is the cyclization of the 3'-nitro-4'-methoxy-diphenyl amine-2carboxylic acid (I) which ought to give two isomers, the 1-nitro-2-methoxy acridine (II) and the 2-methoxy-3-nitroacridine (III). The above acid was formed only by condensation

of 2-nitro-4-amino anisole with o-chloro penzoic acid, and

sov/79-28-8-43/66

not, as expected, with a anthranilic acid (difficult purification of the resinified final product !). The cyclization of the formed 3'-nitro-4'-methoxy-diphenyl amine-2-carboxylic acid by means of phosphorus oxychloride gave the 1-nitro-2methoxy-9-chloroacridine, which has hitherto not been described. It was proved that only one of the possible two isomers is formed in this cyclization. For the verification of the structure of this isomer the 4-methoxy-5nitro-diphenyl amine-2-carboxylic acid, also hitherto unknown, was synthesized and converted into 2-methoxy-3nitro-9-chloro acridine. There are 1 figure and 5 references, 3 of which are Soviet.

binding and that from it 3-ethyl pyrazoline forms. The structure of this matter was proved by the following methodu: 1) by means of the mercury method (ref 9) 97.8 % of acetyler. hydrogen (acetylene end grouping) were found in this matter. 2) A considerably intensive band of the conjugated acetylene and grouping (2100 cm-1) was observed in the infrared spectrum, moreover, an intensive band of CH oscillations of acetylene hydrogen (3280 cm⁻¹), and finally the frequency around 1700 cm-1 (ref 1) characteristic of acetylenes. The frequencies characteristic of the vinyl group in the range between 900 and 100 cm-1 lacked in the spectrum. A considerably intensive band 1526 cm-1 corresponded to the double binding. In order to solve the position of the double binding in the cycle the authors recorded the infra-red spectrum of pyrazoline In this case a higher frequency 1585 cm-1 corresponds to the double bindings. Due to this reason a conjugation of the double and the acetylene binding takes place in the produced ethinyl pyrazoline since reduced values of the infra-red frequencies correspond to these two bindings. Thus, it was

TITLE:

Interaction of Vinyl Acetylene and Its Homologues With

Benzonitrile Oxide

PERIODICAL:

Doklady Akademii nauk SSSR, 1960, Vol. 135, No. 3,

pp. 631 - 633

TEXT: The authors report on their experiments to clarify the mode of addition of benzonitrile oxide to enin hydrocarbons. Further, they tried to produce, in this way, crystalline derivatives suitable to identify enin hydrocarbons. The experiments showed that benzonitrile oxide can be only added to the double bond of a) vinyl acetylene, b) vinyl-methyl acetylene, and c) vinyl-ethyl acetylene. 3-phenyl-5-ethinyl-2-isoxa-zoline (I) is formed in case a), 3-phenyl-5-methyl-ethinyl-2-isoxa-zoline (II) in case b), and 3-phenyl-5-ethyl-ethinyl-2-isoxazoline (III) in case c), according to the following scheme:

Card 1/3

Interaction of Vinyl Acetylene and Its Homologues With Benzonitrile Oxide

s/020/60/135/003/031/039 B016/B054

$$c_{6}H_{5} - c = N - O + CH_{2} = CH - C = C - R \rightarrow CH_{2} - CH - C = C - R$$

$$c_{6}H_{5} - C = O$$

where R=H (I), CH₃-(II), or C₂H₅-(III). The structure of the resulting substances (I)-(III) was determined by the following methods: on the basis of infrared spectra; by the mercury method in the case of substance (I). The same 3-phenyl-2-isoxazoline-5-carboxylic acid was obtained from all three substances by oxidation with alkaline potassium permanganate solution. The authors think it probable that benzonitrile oxide (like diazomethane, Ref.1) is added as a nucleophilic reagent to the double bond of enin hydrocarbons. All three substances synthesized are crystalline and well suited to identify the initial enin hydrocarbons. The reaction mentioned at the beginning may also serve as a passable method of producing isoxazolines with acetylene radicals. There are 1 figure and 6 references: 2 Soviet, 1 US, and 3 Italian.

TITLE: Technological lubricants for cold rolling of sheet and thin plate

SOURCE: Fiz.-khim. zakonomernosti deystviya smazok pri obrabotke metallov davleniyem. Moscow, Izd-vo AN SSSR, 1963, 80-88

TOPIC TAGS: cold rolling, rolling mill, jubricant beef tallow, castor oil, palm oil, mineral oil, sţainless steel

ABSTRACT: The usually applied 2% emulsion of standard emulsol for cold rolling of sheets is not satisfactory, causing high contact pressure between metal and rolls, enhancing formation of carbon deposit and thus preventing eventual tinning, and not permitting rolling of sheets thinner than 0.25 mm. Therefore, other technological lubricants have been tried, such as refined cottonseed oil, hydrogenated sperm oil, palm oil, beef tallow, castor oil, and hydrogenated vegetable oils. Best results in rolling have been obtained with beef tallow and castor oil. However, beef tallow has caused clogging of drain pipes, due to its high melting point. For the same reason hydrogenated sperm oil has proven to be inadequate. Cotton-

Card 1/4

ACCESSION NR: AT4014063

seed oil has been ruled out for its high cost. Palm oil and castor oil have been accepted as best and have been the basic lubricants for sheet rolling during the last three years. However, these oils also have substantial deficiencies. Palm oil is oxidized considerably after storage times above six months, and consequently loses its effectiveness as lubricant; also, it is an imported item. With castor oil, it is difficult to obtain uniform sheet thickness in rolling; furthermore, it is a scarce product. Hydrogenated sunflower-seed oil has been proposed and tried as lubricant for sheet rolling (lubricant PKS-1) and has been found to be nearly equivalent to palm oil. It has been found that by application of effective technological lubricants on one-unit rolling mills, the production can be raised by 30-40% because of reduction of number of passes from 3 to 2. On three-unit rolling mills, rolling of sheets can be done down to a thickness of 0.20 to 0.22 mm; also, an intermediate anneal can be abolished in rolling of No.28 and 32 sheets. Furthermore, it has been found that failures of rolls and bearings are reduced, and the quality output of timplate is raised up to 95%. However, lubricant PKS-1 is made from raw food material. Therefore, since 1960 a search for new technological

Card 2/4

ACCESSION NR: AT4014063

lubricants has been under way. Mineral oils of various viscosities, mineral oils with addition of different fatty acids and vegetable oils, and, for comparison, pure vegetable oils have been tested on a one-unit rolling mill. It has been found that lubricants of higher viscosity correspond to higher stretching coefficients in rolling. The best of the tested mineral lubricants has been cylinder oil No.6. However, difficulties have been experienced in spreading this viscous lubricant on the work. Therefore, preference has been given to cylinder oil No.24 (viscosin), which is equivalent to PKS-1 with respect to stretching of sheet and power requirement but approximately 40 times less expensive. However, the surface quality of sheets has been different when using viscosin or PKS-1. With PKS-1 a shiny smooth surface has been produced, while with viscosin the finished surface has been dull, with white spots from rolled-in oil which sometimes made complete degreasing difficult. It has been concluded that high viscosity mineral oils can be advantageously used as technological lubricants in cold rolling of thin sheets and plates, instead of expensive oils of vegetable or animal origin. For manufacture of cold rolled stainless sheets of 0.8-1.4 mm thickness, strips 1.5-1.8 mm thick have been subjected to intermediate heat treatment and pickling, and then rolled to final thickness. Spindle oil has been used as the lubricant. Under such conditions a great amount of rework was needed and the sheet quality was low.

والمها المراجع والمراجع والمرا

Cord 3/4

ACCESSION NR: AT4014063

Instead of the above procedure, cold rolling of stainless steel strips of 0.7;0.8; 0.9;1.0;1.2;1.3; and 1.4 mm from prerolled sheet 3 mm thick without intermediate heat treatment has been adopted. Such rolling has been made possible by using polished rolls and P-28 oil and viscosin, as lubricants. Total reduction of sheet thickness without preliminary heating has been increased from 50-55 to 77%, not only for austenitic but also for steels of lower plasticity, such as austenitic-ferritic, austenitic-martensitic, and ferritic-martensitic stainless steels without occurrence of edge tearing. The number of passes for rolling 0.8 and 1.0 mm thick strips has been reduced from 14 and 12 to 11 and 9, respectively; surface quality has improved, and driving power and pressure on rolls have not been excessive. Production has been increased by 70%, by applying higher speed with fewer passes. For rolling of 1.5-2.5 thick stainless strips, spindle oil has been retained as the lubricant. The use of high viscosity mineral lubricants, such as viscosin, has proved adequate also for cold rolling of thin (0.35 mm) transformer steel sheets. Orig. art. has: 11 tables.

AUTHORS: TITLE:

Investigation of the Effect of Electromechanical Treatment on the Strength of Metal Ceramic Materials on a Silicon Carbide Base

Inzhenerno-fizicheskiy zhurnal, 1959, Nr 6, pp 100-103 (USSR)

PERIODICAL:

ABSTRACT:

The ordinary mechanical working of materials based on silicon carbide is rather difficult in view of their considerable hardness. There-

fore, the authors studied a possibility of applying electromechanical working and its effect on the strength of metal ceramic materials.

The specimens were prepared by the powder metallurgy method with impregnation and divided into 6 portions, one of which was left without working and the other five were subjected to electromechanical

working with different degrees, of fineness on a special installation. The effect of treatment on the strength was investigated by statical bending with a concentrated force, and the results are presented in

Table 1 and Figure 3. It is shown that the working affects the strength of the silicon carbide specimens considerably, and the latter

GOVERAGE: The book contains 27 articles dealing with principal results of theoretical and experimental investigations of energy dissipation in mechanical vibrations carried out in the Soviet Union from 1956 to 1958. Problems of energy dissipation in materials and factors affecting it are discussed. Purportedly new methods of experimental investigation of damping of vibrations are presented. Attention is given to the recently developed nonlinear theory of calculating vibrations in elastic systems, taking energy dissipation into account. Attempts to analyze internal energy dissipation in materials using methods of mathematical statistics are discussed. Some articles deal with engineering problems in dynamics, in which damping is claimed to play a highly substantial part. Aspirant N. I. Mukhin, of the Kiyev Polytechnic Institute, is mentioned. References accompany some of the articles.

AUTHOR: Applying the methods of mathematical statistics to analyzing the process of energy dissipation in a TITIE: material Referativnyy zhurnal. Mekhanika, no. 9, 1961, 48, abstract 9 V437 (Tr. Nauchno-tekhn. soveshchaniya PERIODICAL: po dempfirovaniyu kolebaniy, 1958, Kiyev, AN USSR, 1960, 71-83) An attempt is made to find the dependence for characteristics of damping properties of a material on the basis of the assumption that energy dissipation in the material is caused, in the first place, by microplastic deformations, using methods of mathematical statistics for taking these deformations into account. Influence of some structural factors on these characteristics is considered, such as the dimensions of the specimen, the form of the Card 1/2

Applying the methods...

S/124/61/000/009/055/058

stressed state, etc. The author finds: 1) An analytic expression for the energy dissipated by the volume unit of the material during a cycle of vibration; 2) relations for relative cyclic viscosity in different forms of stressed state. It is shown that the energy dissipated in the material during one cycle of vibration depends essentially on the structural properties of the material, dimensions of the specimen, form of stressed state. TITLE:

Some Questions Relating to the Strength of Powder-metallurgical Materials on a Silicon Carbide Basis

PERIODICAL:

Inzhenerno-fizicheskiy zhurnal, 1960, Vol. 3, No. 1, pp. 103 - 107

TEXT: In the present paper, the use of the statistical theory of strength in calculating brittle powder-metallurgical materials (silicon carbide) is dealt with. Equation (1,2) by W. Weibull (Refs. 2,4) on brittle strength is mentioned. The tests were carried out at normal (20°C) and high (1200°C) temperatures on silicon carbide samples, which had been produced according to different technological methods, and had a certain similarity to silicates. The photograph of the microsection of a silicon carbide material is shown (Fig. 1), from which its phase-composition may be seen. The results of the tests carried out on 6 silicon-carbide mixtures with different phase compositions for the purpose of determining the brittle strength F are given (Table 1). The curves for the change of the strength F of the samples as dependent on the working volume $v^{1/3}$ were

Card 1/2

Some Questions Relating to the Strength of Powdermetallurgical Materials on a Silicon Carbide Basis s/170/60/003/01/18/023 B022/B007

determined on the basis of the results of bending tests by the application of a concentrated force (Fig. 2). The experimental (F) and theoretical (F*) results for various kinds of state of stress are compared (Table 2). The results obtained show good agreement between experimental data and those obtained according to W. Weibull's calculation formulas. The sensitivity to stress concentrations is calculated and the experimentally obtained quantities q are compared to the calculated values q_r (Table 3). On the basis of the results obtained it may be said that the laws in the destruction of brittle powder-metallurgical materials on a basis of silicon carbide have a statistical character, and that for their sufficiently accurate determination the formulas of the statistical theory of strength by W. Weibull may be used. T. Kontorova and Ya. Frenkel' (Ref. 1) as well as G. Neyber (Ref. 5) are mentioned. There are 2 figures, 3 tables, and 5 references, 3 of which are Soviet.

by investigating the fatigue strength of steel EI612 and of the cermets according to the usual method are given in Fig. 3. Fig. 4 shows the results obtained by investigating the same materials in the case of increasing stress. In tests carried out with symmetric stress cycle, the preliminary of least squares was used. The results obtained by using various methods of determining the fatigue limit are given in a table. From this table and from the Figs. 3 and 4 it follows that when using the method of increasing and also at increased temperature. The saving of time made possible by this method is about 40% for steel EI612 in comparison to the statistical methods. There are 4 figures, 1 table, and 4 references: 1 Soviet, 1 French,

TITLE:

Some problems concerning the fatigue strength of ceramic materials

PERIODICAL:

Referativnyy zhurnal, Mashinostroyeniye, no. 2, 1962, 25, abstract 2A54 ("Wytrzymałość zmęczeniowa tworzyw i elementów metalowych".

Warszawa, 1961, 57-60, Polish)

The authors present the results of investigations of the effect of temperature, mechanical working, presence of notches and also of the stress sign on the fatigue strength of ceramic materials on the base of chromium carbide (85% Cr_3C_2) and silicon carbide (49, 22% SiC). The specimens on the Cr_3C_2 base had the following composition (in %): Ni - 15.3, C - 9.4, Cr - 71.35. They were manufactured by pressing the powder mixture and subsequent sintering in a hydrogen atmosphere at 1,300°C. Static and fatigue tests were carried out on the rough specimens, ground by the mechanical and electrolytic method. The specimens on the SiC base were made from graphite of the corresponding dimensions and shape and then impregnated with Si in a hydrogen atmosphere. The specimens were heated in the machines by resistance currents. The temperature was measured

with optical pyrometers. The tests on the MM-2 (IM-2) machine were carried out at a loading frequency of 50 cps. The 1M-5 (1I-5) machine is intended for pure bending tests with simultaneous tension or compression, at a frequency of 400 cps. The stresses in the specimens were determined from the magnitude of the specimen oscillation amplitude, rated with a microscope. During the tests on the IM-2 machine, the cycle asymmetry attained 0.15, this value being 0.8 on the 1I-5 machine. It was found that a considerable scattering of the fatigue test results could be observed in ceramic materials. The authors recommend to use statistical methods in processing the experimental results. The inflection of the fatigue strength curve in the semilogarithmic coordinates occurs at a base of 106 cycles. The fatigue strength depends on the temperature and surface state of the specimens. In ceramics on the base of Cr3C2, the fatigue limit is considerably lowered if stress raisers are present. The fatigue strength abruptly decreases if axial tensile stresses act on the specimens, and increases in the presence of axial compressive stresses. During cyclic loading, in most of the cases the fracture has no two clearly expressed zones (fatigue and brittle fracture zones). The mentioned zones could be only observed in fractures of SE specimens at high temperatures and considerable axial compressive stresses. There are 9 figures.

TITLE:

The effect of machining on the strength of brittle sintered

materials

PERIODICAL:

Referativnyy zhurnal, Mashinostroyeniye, no. 11, 1962, 39, abstract 11B227 ("Poroshk. metallurgiya, no. 5, 1961, 65 - 68, English summary)

TEXT: The effect of machining on the strength of sintered materials on chromium carbide and silicon carbide base was investigated. Sintered materials on silicon carbide base were tested for strength prior to machining (afterelectromechanical processing), whereby a surface layer 0.5 - 0.6 mm thick was removed, and also after applying to the machined surface a silicon carbide layer. Sintered materials on chromium carbide base (9.4% C, 71.35% Cr, 15.3% Ni and 3.95% others) were subjected to static (pure bending) and fatigue tests prior to machinothers) were subjected to static (pure bending) and electromechanical ing immediately after sintering, abrasive disk grinding and electromechanical processing. It is established that the electromechanical processing as well as the silicon impregnation process increase the static strength of sintered materials.

rials on silicon carbide base prepared by the method of impregnation. Electromechanical processing of sintered materials on chromium carbide base does not reduce the static and fatigue strength, whereas abrasive grinding even under soft conditions reduces considerably both strength characteristics. Such a reduction of strength is caused by the formation in the process of grinding of a large number of superficial microcracks 5 - 10 mm wide (?) and up to 50 mm deep (?). The formation of these cracks is connected obviously with the heating of local surface sections which can produce considerable thermal stresses. It is pointed out that the strength of ground samples is similar to that of the samples with stress concentrators. The microcracks weaken the samples in the same way as the stress concentration of sintered materials on chromium carbide base is 0.4. There are 5 references and 2 figures.

TITLE:

An Investigation of the Fatigue Strength of Steel

1X13 (1Kh13) in Variable Bending With Static Tension

PERIODICAL: Energomashinostroyeniye, 71961, No.4, pp.29-31

Analysis of turbine blade breakages shows that they are TEXT: mostly due to fatigue. In most laboratory fatigue tests certain factors are not allowed for, including the presence under service conditions of appreciable tensile stresses due to centrifugal The present work describes an investigation of the influence on the fatigue strength of steel 1Kh13 in bending of a constant tensile stress which imitated the influence of centrifugal force. The tests were carried out at temperatures of 100 and 400°C on steel 1Kh13 with different kinds of heat treatment. The specimen geometry is shown in Fig.1. The heat treatment and the mechanical properties of the material is shown in table 1, where the second column gives the heat treatment
