AUTHORS: Vavilova, T. I., Gel'chinskiy, B. Ya.

TITLE: A theoretical model of an explosion carried out near the interface

SOURCE: Akademiya nauk SSSR, Institut fiziki Zemli. Trudy, no. 15 (182),
Moscow, 1960, Seismicheskiy effekt podzemnykh vzryvov, 102-108

TEXT: The present article shows that the sign of the first arrival of a longitudinal explosion wave will remain positive even if the center of expansion is located near or on the interface of the elastic constants and that the waves arriving first are of a considerably higher intensity than those following a little later. Based on the general principles of the radial method given by I. G. Petrashen', A. S. Alekseyev, B. Ya. Gel'chinskiy (Ref. 2: Elementarnaya teoriya rasprostraneniya voln [Elementary theory of wave propagation]. V. sb. "Voprosy dinamicheskoy teorii uprugikh voln", vyp. III, izd. LGU, 1958.), the examination of formulae and tables for the refraction factor and the formation of head waves taken from the paper of G. I. Petrashen' (Ref. 3: Materialy kolichestvennogo izucheniya dinamiki seismicheskikh voln [Data of a quantitative study of the seismic

A theoretical model of an explosion ...

wave dynamics]. T. 1-3, 1957-1958.), the authors maintain that the sign of the first motion of longitudinal waves arriving first at any point of the medium will be defined by the sign of the function of the source direction. Hence it appears that the direction of the first motions of the u^+ , u^- fields of the source, and consequently that of the u field, correspond to the compression wave. Due to the practical importance of the intensity ratio of various longitudinal waves appearing in the case under study, the authors examine the waves corresponding to the longitudinal wave fronts. By the formula

$$u = \frac{1}{2} (u^+ + u^-), \quad (1)$$

as well as by formulae of the radial method (Ref. 2) a calculation has been developed whose final formulae help to determine the source fields u_I , u_{II} , u_{III} , and u_{IV} for the \tilde{P}_q wave (front zone I), the \tilde{P}_r wave (front zone II), the $\tilde{\tilde{P}}_r$ wave (front zone III), and the $\tilde{P}_q \tilde{P}_r$ wave (front zone IV). The results of the calculation are given in the form of theoretical seismograms

Card 2/3

of longitudinal waves in which each set of curves defines the function of the direction of the source investigated in the case of a predetermined ratio of constants. They show that wave III is weaker than the preceding head wave with a positive first arrival. It is concluded that the distinctive feature of underground explosions, i.e. the positive direction of the first arrival, is also present when the explosion takes place near the plane interface. There are 5 figures and 4 Soviet-bloc references.

1460. Micro-preparation of derivatives for identification of organic compounds. N. D. Cheronis and A. Vayenas (*Mikrochem. mikro-Makrochim. Acta*, 1951, 58, 428-443).—The purity of reagents is of great importance in preparing derivatives for identification by micro-m.p. etc. The factors to be controlled in the prep. of derivatives to obtain good yields are outlined. The purity of 3 : 5-dinitrobenzoates derivatives of alcohols is greatly increased by pulverizing the crude product before washing it with 3% aq. Na_2CO_3 at 60°. One crystallization then gives a pure product. The principal impurity in α -naphthylacetanilide is a compound of lower m.p. than the acetanilide. It may be removed by fractional micro-crystallization. Micro-apparatus for organic synthesis is described. (81 references.)

TITLE: Sorption of indium from certain aqua-organic solutions by cation exchanger
KU-2

SOURCE: Ref. zh. Metallurgiya, Abs. 9G173

REF SOURCE: Sb. Jonocobmen. tekhnologiya. M., Nauka, 1965, 80-83

TOPIC TAGS: ion exchange, indium, sorption

ABSTRACT: The sorption of In from aqueous, aqua-acetone, aqua-ethanol, and aqua-ethanol-chloroform solutions by the cation exchanger KU-2 was investigated. Practically no absorption of In by KU-2 occurs in nonaqueous acetone solution. Addition of small quantities of H₂O to acetone causes a sharp increase in the degree of sorption. Maximum sorption for the hydrogen form of the ion exchanger (~ 99%) is reached at 15 vol % H₂O. The ammonium form of the cation exchanger sorbs In somewhat less effectively. Increasing the amount of water decreases sorption (in pure water, it did not exceed ~ 80%). In pure acetone, which has a low dielectric constant, the In salt is considerably less dissociated as compared with the dissociation in the presence of small amounts of water. Maximum sorption in the presence of small amounts of water in solution may occur for sorption of neutral

UDC: 669.872.09

Card 1/2

L 46105-66

ACC NR: AR600043

molecules which decreases with increase in the H_2O content of the solution. In solutions containing ethanol and ethanol with chloroform, the rate of sorption is smaller than in aqueous solutions. The dielectric constant in the above solutions decreases in the order:

The calculated ion exchange constants are: 0.289 for solutions containing H_2O , 0.125 for $H_2O + C_2H_5OH + CHCl_3$ (in the ratio of 5:6:1), and 0.087 for $H_2O + C_2H_5OH$ (in the ratio 3:7). 3 illustrations, 1 table. Bibliography of 6 citations.

TEXT: In most existing methods of focussed photography in x-ray structural analysis, full focussing is attainable for a single line only, with part-focussing being partially possible for lines in the direct vicinity of the former. The exception to this rule is the Zesman-Bolin / Abstracter's note: Transliterated ✓ method, in which the condition of focussing is satisfied for all lines; the above method, however, requires complex equipment. The new method consists in that a flat cassette of simple construction is placed in such a manner that the 2 extreme lines of a definite angle interval be accurately focussed. If the angular spacing of these two extreme lines is not too great, the focussing circle intersects the film at

Card 1/2

A method of focussed ...

Abstract : X-ray cameras have been prepared with attachments for cooling the specimens to -130° as the specimens are being X-rayed in accordance with the classical Debye-Scherrer method, by the backward photography method, and by the self-focusing method. The specimen is placed in a celluloid tube, through which gas cooled with liquid air is passed.

AUTHOR: Vavra, F.

TITLE: A method of preparing thin sheets of AgCl and AgBr by capillarity

SOURCE: Chekhoslovatskiy fizicheskiy zhurnal, v. 13, no. 11, 1963,
846-849

TOPIC TAGS: thin plate, single crystal, crystal growing, capillary crystal growing, silver chloride, silver bromide, thin plate preparation, polycrystalline plate, silver halide single crystal, silver halide

ABSTRACT: A method of utilizing capillary action for producing thin plates of silver halides is described. In the preparation of thin sheets of pure silver chloride, blocks of ten or more glass microscope slides measuring 78 x 26 x 1 mm and separated by gaps of 0.2 mm are assembled in the vertical position on a porcelain base. A measured amount of granulated AgCl is poured around the blocks, melted, held for 30 min at a temperature several degrees higher than the

Card 1/2

ACCESSION NR: AP4000006

melting temperature, and then cooled slowly to room temperature. Due to the capillary action, the melt fills the gaps between the slides, and the thin plates after cooling are separated from the slides and the base by immersion in distilled water containing a few drops of hydrochloric acid. To obtain plates with large grains (up to several square centimeters), the block is reheated in 40 min from 20C to several degrees above the melting temperature, held there for 30 min, cooled rapidly to 350C, held at this temperature for 2 hr, and then furnace cooled. The above method can be used to obtain thin single-crystal and polycrystalline silver chloride or bromide plates with good surface quality. The basic principle of the method may also be applied to the preparation of thin plates from other materials. Orig. art. has: 3 figures.

AUTHOR: Vavra, Irzhi (Czechoslovakia)

TITLE: Variation in magnetic characteristics of spherical magnetites
manufactured by the "wet" method

SOURCE: Tekhnika kino i televideniya, no. 7, 1964, 32-35

TOPIC TAGS: ferromagnetic iron oxide, ferromagnetic iron oxide
characteristics, ferromagnetic iron oxide production

ABSTRACT: An investigation of the author's method of production of ferro-magnetic iron oxides (Chem. listy, 1958, 52, 573) based on the earlier method of A. Kaufman and F. Haber (Z. Elch. angew. phys. Chem., 1909, 733) is described. The author's method is characterized by the fact that (1) the operation of FeO-hydrate precipitation is separated from the operation of oxidation and (2) NaOH is used as a precipitator and NaNO₃ as an oxidizer.

Card 1/2

ACCESSION NR: AP4042132

Spherical magnetite was prepared by these two versions of the method: (A) An acidified aqueous solution of ferrous sulfate was added to an aqueous solution of NaOH at pH = 12.3-12.4, and then the precipitated FeO hydrate was oxidized by NaNO₃; temperature was 20-90C; a protective nitrogen blanket was used in some of the experiments; (B) Same, but the precipitated and stabilized FeO was oxidized by a batched amount of pure oxygen or air oxygen. It is found that, under the above conditions and using a strong oxidizer (oxygen), the content of a nonspinel nonferromagnetic rhombohedral component increases as the process temperature decreases below 60-70C; this component affects the magnetic qualities of the final product. Orig. art. has: 7 figures, 2 formulas, and 1 table.

TITLE: Modification of Zimm's diagram for the calculation of the radius of gyration

PERIODICAL: Chemické Zvesti, no. 1, 1963, 54-56

TEXT: The present work is a continuation of earlier investigations by the author with the difference that the radius of gyration was calculated for extracted natural rubber. The calculation of the limiting curve $c = 0$ is rather complicated in this case and the author used a modified Zimm diagram as suggested by J. T. Yang (J. Polymer Sci., v. 26, 1957, 305). The curves are characterized by the equation:

$$(Kc/R_0)^{-1} = f(\sin^2 \frac{\theta}{2} + kc)$$

Card 1/2

Modification of Zimm's ...

Z/043/63/000/001/004/004
D287/D307

which is in good agreement with the equation $y = 1/a + bx$. A value of 700 Å was obtained for the gyration radius of extracted natural rubber, calculated on the basis of the limiting curve for $c = 0$ in an upward direction.

AUTHOR: Vavra, Jozef

TITLE: Application of Zimm's method for determining the
molecular weight of natural rubber

PERIODICAL: Chemické zvesti, no. 1, 1960, 3 - 7

TEXT: In this article the average molecular weight is established of extracted and non-extracted natural rubber by Zimm's extrapolation method, during which the intensity of the diffused light was measured visually. Natural rubber (*Hevea Brasiliensis*) was used. The extraction was made by a mixture of acetone and methanol 1:1 cold. The conventional solvents (toluene, benzene) were not suitable for diffusion measurement, due to the small difference of refraction indices of the solution and the solvent. Therefore, pure cyclohexane, rectified and dried by metallic sodium was used. The concentration of the solutions was determined by vaporizing the solvent first in the air and then by drying it to

Card 1/5

SLOV/003/60/000/001/001/002
D214/D304

Application of Zimm's ...

a constant weight at 600°C in vacuum. The concentration range was $1 \cdot 10^{-3}$ to $3 \cdot 10^{-3}$ g/ml. The difference of the refraction index between the solution and the solvent was measured with a Zeiss laboratory interferometer. The intensity of the diffused light was measured on the visual instrument which was described by F. Sokol (Ref. 4: Chem. zvesti, 10, 1956, 322-329). The original 40 W mercury vapor lamp was replaced with 160 W Philar lamp of Czech adaption which considerably improved the accuracy of the photometer readings. The functioning ability of the measuring equipment was proved by size determination of the particles of the polystyrene. The obtained value of the diameter of the spherical particle of polystyrene (920 Å) was in close agreement with the given electro-optically determined value of 880 Å, during which the permissible error was ± 80 Å. Carbon disulphide was used as a standard for the diffusion measurement, during which the value $44.2 \cdot 10^{-6}$ at 5460 Å was taken as its non-corrected Rayleigh's constant. The value R_g , determined for the solvent, was subtracted from the data

Card 2/2

SLOV/003/60/000/001/001/002
D214/D304

Application of Zimm's ...

for the solution. The value of the refraction index increment for the cyclohexene solution of the extracted rubber 0.0946 was in close agreement with the value 0.0943, obtained with the differential refractometer. For the non-extracted rubber, the value of 0.145 was determined. The molecular weight was calculated per relation

$$\lim_{\substack{\lambda \rightarrow 0 \\ \theta \rightarrow 0}} \frac{R_\theta^n}{c} = [R] = \frac{2 \cdot \pi^2 \cdot n_0^2 \cdot (\partial n / \partial c)^2}{\lambda_0^4 \cdot N} \cdot M_w = K \cdot M_w.$$

whence $M_w = \frac{[R]}{K}$, where $[R]$ is the so-called internal diffusion, M_w is the weight average of the molecular weight, c = concentration in g/ml, n_0 = refraction index of the solvent, n = refraction index of solution, $\partial n / \partial c$ = refraction index increment for the wave length λ_0 (in vacuum, in centimeters), N = Avogadro's number, R_θ^n = reduced intensity of diffused light for the angle θ and non-

Card 3/5

SLOV/003/60/000/001/001/002
D214/D304

Application of Zimm's ...

polarized primary link given by the relation

$$R_{\theta}^n = \frac{44.2 \cdot 10^{-5} (f_r - f_p) \cdot n}{f_s} \cdot \frac{\sin \theta}{1 + \cos^2 \theta},$$

where f_r is photometer reading for the solution, f_p is for the solvent and f_s is photometer reading for the standard, n is the correction for the divergency of diffused links. Zimm's gratings of extracted rubber and non-extracted rubber are given. The differences between them are striking. The typical straight line grating is obtained for the non-extracted rubber while for the extracted rubber the grating is curved. It is possible to explain this difference by the fact that through extraction and elimination of the natural mixtures (antioxygens), probably the individual segments of the molecule coil approached each other, internal bonding took place as well as thickening of the coil without any change in

Card 4/5

Application of Zimm's ...

SLOV/003/60/000/001/001/002
D214/D304

the molecular weight. The natural antioxogens are bound to certain places -- active centers -- so that for steric reasons, the tight winding of the coil is impossible. The author concludes that determination of the molecular weight of the extracted and non-extracted natural rubber by applying Zimm's extrapolation method led to the elaboration of a new method of suitable concentration. The value of 550,000 for the extracted and 570,000 for the non-extracted native rubber was determined. There are 4 figures and 7 references: 4 Soviet-bloc and 3 non-Soviet-bloc.
