TITLE: Turbine Shaft and Rotor Shape Retention at Elevated Temperatures
(O stabil'nosti formy turbinnykh valov i rotorov pri povyshennykh
temperaturakh)

PERIODICAL: V sb.: Prochnost' metallov. Moscow, AN SSSR, 1956, pp 67-80

ABSTRACT: An investigation is made of the thermal instability (TI) of turbine shafts and rotors, consisting of the appearance of elastic distortions at elevated temperatures. It is shown that distortions in turbine parts that have seen long service is usually related to a unilateral local grazing of fixed turbine parts by rotating details. A characteristic peculiarity in these cases is the fact that the zone of grazing is asymmetrical relative to the axis of rotation. Grazing results in a considerable local rise in temperature, often resulting in surface fusion of the metal, even if friction is low. It is shown that at elevated temperatures, residual distortion of shafts will occur upon the formation or relaxation of local internal residual stresses (RS), a sketch of the distribution of which will be asymmetrical relative to the axis of the rotating part. Formation of internal RS in turn induces inhomogeneity of changes in depth due to local heating and grazing in the

Card 1/2

SOV/137-57-11-22295

Turbine Shaft and Rotor Shape Retention at Elevated Temperatures
process of operation. These phenomena occur as the result of violation of the normal process procedures in turbine manufacture and repair: Inadequate temperature at the end of forging operations, uneven hardening, excessive cooling of a part on one side during normalization, etc. The phenomenon of TI is also induced by asymmetrically oriented structural inhomogeneities in shaft and rotor metal. Certain recommendations are made on the prevention and elimination of TI. It is noted that a necessary condition for stability in the shape of a part is elimination or reduction of internal RS in the manufacturing process. Toward this end it is recommended that normalization followed by high-temperature tempering ($>600^{\circ}\text{C}$) be undertaken appropriate to the relaxation properties of the steel. The part should be cooled with the furnace at a cooling rate of $30-50^{\circ}\text{C}$ per hour, which guarantees that minimal RS will result. Elimination of TI is facilitated by thermal stabilization of turbine rotors after machining at temperatures similar to the temperatures at which the forging was tempered. In addition to improvements in the techniques of the final heat treatment it is also recommended that certain refinements in shape be made, so as to render the rotor design easier to produce (Making the transition from the shaft journal to the disk in the form of a deepened stress-relieving groove, etc.).

TITLE: Investigation of the structure, properties, and inner residual stresses of weld joints in main steam pipes from austenitic steel of the type 3M -257 (EI-257)

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 6, 1962, 6, abstract 6E35 (V sb. "Ekspluatats. nadezhnost' metalla parosilovykh ustanovok", Moscow-Leningrad, Gosenergoizdat, 1959, 5 - 15)

TEXT: To clear up the effect of the thermal treatment technology of steam pipes with super-high parameters upon their exploitation safety, tests on the aging of steel, the structure and property of the weld joints before and after thermal stabilization were made. Weld joints of tubes with diameter 219 mm and wall thickness 27 mm were investigated. The tests were carried out: 1) after welding, 2) after welding and subsequent thermal stabilization (800°C during 10 hours), 3) after welding with a special form of strengthening the multilayer seam, which allowed to lower the residual stresses. Conclusions: 1. Thermal stabilization (800°C during 10 hours) effects a considerable change in the struc-

ture of the metal with separation of a secondary phase (high-chromium carbides + α -phase), chiefly along the grain boundaries, the sliding lines, and twinning lines. 2. This aging process makes the metal more brittle, which is to observe by the change of plasticity in the notch. 3. The brittleness after thermal treatment increases with the aging of the steel during exploitation. The most stressed state of a weld joint during service in exploitation is the first period of aging, throughout the disperse separation of the second phase. 4. The total level of residual stresses after welding is relatively low ($\leq 8 \text{ kg/mm}^2$). 5. The thermal stabilization lowers the residual stresses by approximately 60%. But considering the absolute value of residual stresses ($\approx 5 \text{ kg/mm}^2$) the application of stabilization under assembling conditions shows little effectiveness. 6. High-temperature heating of a welding joint under assembling conditions can effect the formation of plastic deformation and the development of hidden defects in the seam. 7. The thermal stabilization cannot be recommended for the processing of weld joints in power plants of main steam pipes of steel EI-257. 8. The investigated form of the seam secures a relaxation of the residual stresses by 30% during the process of strengthening and can be recommended for the use under assembling conditions.

opluchatelnaya nadezhnost' metalla parosilovykh ustanovok; sbornik statey
(Operational Reliability of Metal in Steam Power Plants; Collection of Articles)
Moscow, Gosenergoizdat, 1959. 126 p. 2,200 copies printed.

Ed. (Title page): I.N. Laguntsov, Candidate of Technical Sciences; Ed. (inside book):
I.K. Korikovskiy; Tech. Ed.: N.I. Borunov.

PURPOSE: This collection of articles is intended for technical personnel of power
stations, power machinery plants, and scientific research institutes.

PAGE: The articles set forth the results of investigations that were conducted
by Otdeleniye metallov, Vsesoyuznyy teplotekhnicheskiy institut imeni F.E.
Dzerzhinskogo (Department of Metals of the All-Union Heat Engineering Institute
imени F.E. Dzerzhinskого) in the years 1955-57. The articles deal with the problem
of investigating new types of steel and of analyzing the causes of damage to cer-
tain parts of power plant equipment. Problems associated with operating dependa-
bility of welded joints in steam piping for high and extra-high pressure boilers
are discussed. The results of investigations of dry pressure "bonding" of metals

Card 1/4

Operational Reliability of Metal (Cont.)

TITLE: Faults in Welded Joints of High-pressure Steam Piping,
and their Notch-sensitivity

PERIODICAL: Teploenergetika, 1959, Nr 10, pp 39-43 (USSR)

ABSTRACT: Many faults in welded joints on high-pressure steam piping in power stations have been revealed by ultrasonic methods. It was accordingly decided to study such faults and to make special tests of notch-sensitivity at high temperatures and under various conditions of stress. The tests were made on damaged welded joints in main steam pipes made of steel grade 15KhM obtained from power stations and also on experimental welds on pipes of 273x27 mm diameter welded under practical conditions with electrodes grade TsL-14. The properties of the joints were studied both before and after tempering at a temperature of 680-710°C. The damaged joints were sectioned and ground to reveal cracks and voids formed by poor penetration, as photographed in Figs 1 and 2. Polar diagrams of damaged joints of the type shown in Fig 3 were constructed, as a means of analysing the development of cracks from the root of the welds. Most of the cracks took place across

Card
1/4

Faults in Welded Joints of High-pressure Steam Piping, and their
Notch-sensitivity

SOV/96-59-10-7/22

the crystals and some were filled with oxide; as photographed in Fig 4. In many cases, the edges of the crack are decarbonised to a depth of several grains; see for example, Fig 5. The analysis showed that failures were of a brittle character starting from places of local stress concentration at the root of the weld. The notch-sensitivity was first studied by short-term static tensile tests, carried out over the temperature range of 20-500 °C. The criterion of evaluation was plasticity of the metal in the notch. The radius of the bottom of the notch was made 0.3 mm and the angle 47 degrees. Tests were made both in the weld and in the main metal and the results are given in Table 1 and in Fig 6. Great variations were found in the properties of the weld metal, particularly if it had not been tempered. The notches used in the tests were not so sharp as natural cracks and there is an obvious risk of sharp cracks developing during the starting-up period at intermediate temperatures around 300 °C. The influence of static load on the notch-sensitivity was also studied in long-term tests. The tests were made at temperatures of 540 °C and

Card 2/4

SOV/96-59-10-7/22

Faults in Welded Joints of High-pressure Steam Piping, and their
Notch-sensitivity

various stresses ranging from 24 to 32 kg/mm². The results are given in Table 2 and show that in general the time to failure is longer in welds that have not been heat-treated. In tests lasting more than 2000 hours tempering is found to give improved performance. Dynamic loads are also applied to piping during erection and operation. Accordingly dynamic tests of notch-sensitivity were made, using specimens of 10 x 10 x 55 mm made from welded joints taken from pipes. Specimens with artificial notches and natural cracks were both tested. The results obtained were used to plot the volumetric diagrams of variations in impact strength of welded joints given in Fig 7. In heat-treated welded joints subjected to bending stresses greater than 10 kg/mm² at room temperature the metal of the zone of melting has a lower damping capacity than the weld metal; at a temperature of 500 °C the position is reversed. The beneficial effect of tempering in reducing the notch-sensitivity is largely to be explained by changes in the structural conditions and relaxation of internal stresses.

Card

Notch-sensitivity

SOV/96-59-10-7/22

Analysis of stresses in piping show that the maximum normal stresses due to internal pressure, which are of the order of 4 kg/mm², are not specially dangerous in magnitude or direction. Apparently the development of cracks is mainly associated with dynamic and additional thermal and uncompensated loadings that occur when pipes are not free to move as they expand. Overloading may also be caused by wrong spacing of the supports, because the pipes then bear too much of their own weight.

Inspection of a large number of welded joints in various high-pressure power stations has shown that they are quite reliable if they are properly made, correctly heat-treated and operated under normal conditions.

TITLE: Brittle failures, the structure and the properties of welded joints of high-pressure pipelines

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 5, 1962, 21, abstract 5E97
(V sb. "Ekspluatats. nadezhnost' metalla parosilovykh ustyanovok".
Moscow-Leningrad, Gosenergoizdat, 1959, 49 - 61)

TEXT: Investigated were the structure and the properties of welded joints of high-pressure pipelines, made from grade 20 and 15 XM (15KhM) steels. To test the welded joints, analyzed were the structural heterogeneity, internal residual welding stresses, the sensitivity of the metal to notches and the fatigue strength. The following conclusions are drawn: 1) The failures of welded joints of pipelines in high-pressure power installations are of brittle-type. 2) These failures, during the initial operational period, are caused by a poor quality of welding. After a long operational period, the failures are due not only to the seam defects - but to the corrosion action of the medium, the effect

Card 1/3

Brittle failures,...

S/137/62/000/005/135/150
A160/A101.

of uncompensated stresses, pulsation of temperatures and pressures, and also to an increased vibration. 3) A considerable difference between the heating temperatures and the rates of cooling the metal during the welding of pipes leads to a great structural heterogeneity. The formation of a Widmanstätten pattern is characteristic of the welded joints of pipes made from 15-20-grade carbon steels. Ferrite-perlite structures with a "radiant texture" will develop in the welded joints of steam pipes from 15 KhM steel. 4) Investigations conducted on butts of steam pipes made from perlite steel and welded by the technology used under assembly conditions warranted a conclusion that the welded joints which had not been subjected to thermal treatment possessed reduced ductile properties. 5) It was detected that the welded joints which had not been thermally treated had an increased tendency to brittle failure. The highest sensitivity to notches possesses the fused-on metal. 6) The maximum residual tensile stresses (σ_{resid}) in steam-joints attain the level σ_s and are located in the built-up metal at a depth of ~10 mm. In the zones of the thermal effect the maximum stresses are on the pipe surface. 7) σ_{resid} form an asymmetric cycle during alternating loads and reduce about twice the cyclic strength of welded joints. 8) A high tempering of welded joints of steam pipes from perlite steel leads to a relaxa-

Card 2/3

Brittle failures,...

S/137/62/000/005/135/150
A160/A101

tion of ~90% of the internal welding stresses, increases the bend angle about two times and decreases the tendency to brittle failure. The operational reliability of welded joints of steam pipes from perlite steel increases after high tempering. There are 8 references.

TITLE: The dependence of the damping decrement of stainless chromium steel on the structure state and mechanical properties

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 4, 1962, 26, abstract 4I152 (V sb. "Ekspluatats. nadezhnost' metalla parosilovykh ustavovok". Moscow-Leningrad, Gosenergoizdat, 1959, 89-97)

TEXT: The damping decrement was determined by the data of measurement of the amplitude of free oscillations at bending the steam turbine blades. Mechanical oscillations imparted to a cantilever-fastened blade, were then transformed in electric ones by means of an induction pickup and recorded with a loop oscilloscope. Maximum bending stress at the root of the working part was 350 kg/cm². More than 200 blades made of material corresponding by the chemical composition to 1X13 (1Kh13) and 2X13 (2Kh13) grades of steel were investigated. Out of the mentioned blades samples were made which were subjected to mechanical tests. Furthermore, an investigation of microstructure of blades with different damping decrement values was carried out. The presence in the structure of

Card 1/2

The dependence of the damping ...

S/137/62/000/004/097/201
A052/A101

excess phases, - free chromium ferrite or free Cr carbides at the boundaries of grains, - reduces the damping decrement. A perlite structure without excess phases secures maximum damping decrement value; b_t , b_s , hardness and δ for blades with different damping decrements practically do not change; a_k and ψ increase with an increase of the damping decrement. An increase of the damping decrement by a factor of 1.5 - 2 (from ρ 0.0171 to ρ 0.0391) has just a little effect on b_w . The obtained data permitted the recommendation of the following optimum composition of stainless Cr steel for working turbine blades: 0.15 - 0.20% C, 11.5 - 13.0% Cr, 0.6 - 0.8% Ni. TITLE: Investigation of the structure and properties of Steel
12XMФ (12KhMF) in the brittle and normal condition

PERIODICAL: Teploenergetika, 1961, No.9, pp. 44-49

TEXT: Steel 12KhMF is used in the Soviet Union as a constructional material in the fabrication of highly stressed components of the steam generating and distributing plant in which the steam temperature may reach 570 °C. A large proportion of tubes made of this steel and intended to form the main steam conduits at several power stations has recently had to be scrapped because of their low impact strength which sometimes was less than 0.5 kgm/cm². Hence the present investigation, whose object was to compare the structure and various mechanical properties of this steel in both brittle and normal conditions. The experimental work was carried out on tubes (273 mm in diameter, 36 mm wall thickness) as supplied from various power stations. The composition of two batches of this material is given in Table 1. Since in many cases

Card 1/10

Investigation of the structure and ... S/096/61/000/009/002/008
E193/E183

regions of low ($< 1.0 \text{ kgm/cm}^2$) and high ($> 15 \text{ kgm/cm}^2$) impact strength were found in one and the same tube, the object of the first stage of the present investigation was to establish what heat treatment would reduce the impact strength of the material studied to $a_k < 1-2 \text{ kgm/cm}^2$. Fifteen different heat treatment schedules were tried and it was found that minimum impact strength ($a_k < 1 \text{ kgm/cm}^2$) is imparted to the steel studied by heating it to 980-1100 °C, cooling it in air or oil, and then tempering at 650°C; similar results were obtained by heating the steel to 1150 °C, holding it at the temperature for 40 minutes and then cooling it at a rate of 50 °C/h to 600 °C. Correlation of these results with the actual heat treatment schedules used during the fabrication of tubes indicated that local embrittlement of the tubes can be caused by departure from the normal heat treatment conditions, which results in parts of the tube being tempered at too low a temperature (approximately 650 °C). It was found also that ductile properties ($a_k > 10 \text{ kgm/cm}^2$) can be restored to a brittle material by simply tempering it at 750. °C, i.e. at a temperature which, while sufficiently high, would not bring the steel into the solid solution (austenite range). The object of the next series of Card 2/ 10

S/096/61/000/009/002/008
Investigation of the structure and.. E193/E183

experiments was to study the structure of the steel in both brittle and normal condition by optical and electron microscopy, X-ray diffraction, and carbide analysis. The results indicated that whereas Steel 12KhMF in the normal condition has a structure consisting of pearlite and ferrite grains with the carbides mainly dispersed in the solid solution, the carbides of the alloying elements in the brittle material are concentrated at the grain boundaries. In the final stage, various mechanical properties of the steel at temperatures up to 570 °C were studied with particular reference to the effect of stress-risers (notches) on the strength and ductility of both brittle and normal material. In addition, internal friction, specific heat, electrical resistivity, and the elastic modulus were measured. The most important results are reproduced graphically. Thus, the temperature-dependence of σ_b and σ_s (UTS and yield point, respectively, kg/mm²) and ψ and δ (reduction of area and ductility, %) of steel 12 KhMF is shown in Fig.1a, curves 1 and 2 (full and open circles) relating to ductile and brittle condition, respectively. The temperature-dependence of impact strength (kgm/cm²) of this steel is illustrated

Card 3/ 10

Investigation of the structure and ... S/096/61/000/009/002/008
E193/E183

in Fig.16, the various curves relating to the following specimens:
1 - normal condition, batch number 1, notch root radius $R_H = 1$ mm,
notch depth $h_H = 2$ mm; 2 - normal condition, batch number 2,
 $R_H = 1$ mm, $h_H = 2$ mm; 3 - brittle condition, $R_H = 1$ mm,
 $h_H = 2$ mm; 4 - brittle condition, $R_H = 0.15$ mm, $h_H = 4$ mm;
5 - normal condition, $R_H = 0.15$ mm, $h_H = 2$ mm; 6 - brittle
condition, tempered at 750°C ; 7 - normal condition, $R_H = 0.15$ mm,
 $h_H = 3$ mm. The notch sensitivity of steel 12 KhMF in the brittle
condition is also illustrated by three-dimensional diagrams
reproduced in Figs. 3 and 5. Fig.3 shows the reduction of area
(%) of notched tensile test pieces, blocks a-8 relating to the
following specimens: a - ductile condition, $R_H = 0.3$ mm,
 $K_t = 4$ (no definition of K_t given); 6 - brittle condition,
 $R_H = 0.3$ mm, $K_t = 4$; 8 - brittle condition, $R_H = 0.1$ mm,
 $K_t = 6.4$. In Fig.5 the impact strength D_k (kgm/cm^2 , vertical
axis) of steel 12KhMF in the brittle condition is plotted against
the test temperature ($^{\circ}\text{C}$, horizontal axis) and the notch depth
(h_H , mm, the third axis); diagrams a and 6 relating to
specimens with the R_H of 1.0 and 0.15 mm respectively. Other
properties of the steel studied were also affected by the
Card 4/ 10

Investigation of the structure ... S/096/61/000/009/002/008
E193/E183

transition from the normal to brittle condition. Thus, the internal friction of the brittle material was 5-10 times lower than that of the steel in the normal condition. The modulus of elasticity of brittle specimens within the entire temperature range studied was also approximately 25% lower than that of normal material. An increase in the electrical resistivity and a change in the electrode potential were observed in the brittle material whose specific heat however was practically the same as that of steel in the normal condition. It was inferred from these findings that the changes in the properties of steel 12KhMF, brought about by its transition to the brittle condition, are more profound than those normally associated with temper brittleness in other constructional steels.

Problemi razpetine v električnem daljnovodu (Span Problems in Overhead Transmission Lines) Ljubljana, Slovenska akademija znanosti in umetnosti v Ljubljani, 1959. 68 p. (Series: Slovenska akademija znanosti in umetnosti. Razred za matematične, fizikalne in tehnične vede. Dela No. 4) (Series: Slovenska akademija znanosti in umetnosti. Institut za električno gospodarstvo. Dela, No. 2) 1,000 copies printed.

Sponsoring Agency: Slovenska akademija znanosti in umetnosti.

PURPOSE: The book is intended for specialists in electrical network design.

COVERAGE: The author discusses two views of the span-length problem: the electrical and the mechanical. Study of the first view, which, as the author claims, probably originated in the United States, considers long spans as more economical and less subject to electric faults. The second view considers long spans as subject to greater mechanical stresses and to metal fatigue at the points
Card 1/3

Span Problems (Cont.)

YUG/3002

of suspension; this point of view, according to the author, has its origin in Germany. The author attempts to find a solution which would take both points of view into consideration and combine economy and safety requirements. No personalities are mentioned. There are no references.

TABLE OF CONTENTS:

Investigation of sorption and desorption of olefins on active carbon. E. V. Alekseevskii and T. G. Vidman. *J. Applied Chem. (U. S. S. R.)* 12, 1343-56 (in French, 1356) (1939).—The sorption and desorption of CH_2CH_2 , MeCH_2CH_3 , $\text{MeCH}=\text{CHMe}$, Me_2CCH_3 , and amylenes with activated C ("AG") and birch charcoal activated with $\text{Zn}-\text{Cl}$ were studied and the adsorption isotherms for those hydrocarbons were constructed. The dynamic activity of birch charcoal was higher than that of "AG" C. The adsorption of these hydrocarbons by each adsorbent increased with an increase in the mol. wt. About 70-98% hydrocarbons of the ethylene series were desorbed from the coal mixt. with superheated (110°) steam and CO_2 . During the sorption and desorption, polymerization of hydrocarbons was not observed, although the catalytic action of C at 600° and higher was noticeably increased.

AUTHOR: Vidmanov, Yu. I.

TITLE: Photocompensating electrometric amplifier FKE-3P

CITED SOURCE: Nauchn. tr. vuzov Povolzh'ya, vy*p. 1, 1963, 218-224

TOPIC TAGS: photocompensating amplifier, electrometric amplifier, impedance amplifier/ amplifier FKE-3P

TRANSLATION: The FKE-3P amplifier is designed for measuring the electromotive force of sources with high internal resistance, and for the measurement of very weak currents. The amplifier can be used to measure high ohmic resistances, electric charges, the electrostatic measurement of capacitance and for other purposes. The unit has a high input impedance (10^1 ohms) and can be used successfully for measurement of radiation in diimeters. It is also suitable for the measurement of the element of potential of static electrical fields. The principle of operation is the same as in other areas. The FKE-3P amplifier operates on the principle of a photocompensator.

Savjetovanje industrijskih elektronicara, Zadar, 1956

Industrijska elektronika; referati odrzani na savjetovanju industrijskih elektronicara u Zadru (Industrial Electronics; Reports Given At the Conference On Industrial Electronics in Zadar, August 6-11, 1956) Zagreb, Komisija za elektroniku drustva alatnicara FNRJ, 1958. 230 p. No. of copies printed not given. No contributors mentioned.

PURPOSE: This collection of reports promotes the use of electric and electronic devices in modernizing industrial plants. It is intended for management and technical personnel of Yugoslav industry.

COVERAGE: The collection contains papers presented during the convention of industrial electronic specialists which took place in Zadar (Yugoslavia) August 6-11, 1956. In these papers, the following problems were discussed: effect of automation on national economy, equipment used for automation of industrial processes, application of radar in modern warfare, industrial television, use of ultrasonics in machining, and computers. In addition to the reports published in this collection, the following papers were presented at the convention:

TITLE: A Discovery of Remains of Bos primigenius Boj. (Nakhodka
ostatkov Bos primigenius Boj)

PERIODICAL: Tr. AN LitSSR, 1956, Bulletin 3 (6), pp 79-83.

ABSTRACT: In the summer of 1955, during excavation of a drainage
ditch through a swamp near the village of Usenay (the
Pageg yay region in the western part of Lithuania),
remains of Bos primigenius Boj. were found. These
remains consist of a skull, a lower jawbone, some
vertebrae, and fragments of ribs. The bones occur at
depths ranging from 60 cm to one meter in a layer of
alderwood peat. Pollen groups from peat samples taken
with the animal bones date the death of the animal at
the end of the Atlantic period (the level of maximum
spruce and alder pollen), two to three thousand years
B. C. The formation of the peat bog may be explained

Card 1/2

1912 Titrations in non-aqueous solutions. IX.
Neutralization titrations in anhydrous formic acid.
J. L. Glaser and J. Vilner, *J. Am. Chem. Soc.* 1943, **65**,
1321-1325. The authors report the following acid-
base titrations in 95 to 99.8 per cent formic acid:
described Na formate, urea, pyridine, sulphapyridine,
betaine, 8-hydroxyquinaline, aniline, ephedrine and caffeine with 0.1 M HClO_4 and
 HClO_4 with 0.1 M Na formate. For potentiometric
titrations a quinhydrone or hydrogen electrode was
used, visual titrations were carried out with gentian
violet, neutral violet, saffronine, malachite green
and orange I as indicators. Removal of water from
formic acid (repeated distillation and freezing out)
is troublesome and formic acid is therefore a less
convenient titration medium than glacial acetic
acid.

TITRATIONS IN NON-AQUEOUS SOLUTIONS. (PART) II.
NEUTRALIZATION TITRATIONS IN ANHYDROUS FORMIC

ACID. Oldřich Tomášek and František Vlček. Translated
from Chem. Listy 67, 531-6 (1973). Available from
Associated Technical Services (Trans. No. 32F4C), East
Orange, N. J. (AEC-tr-1978)

The possibilities of acid-base titrations in formic acid
were studied, and the acidity relations in this medium
were investigated. Scales of analogous compounds were
constructed. It was shown that the course of dehydrations of
formic acid with anhydrous anhydride can be followed potentiometrically, and thus the water content of formic acid can
be roughly estimated. In formic acid solutions dehydrated
by this method, titrations of a series of bases with
perchloric acid solutions in the same solvent and, con-
versely, titrations of this acid with sodium formate were
carried out. The titrations were performed either potentiometrically with a quinhydrone indicator electrode or
visually with the use of gentian violet, crystal violet,
neutral violet, safranine, malachite green, and orange I as
indicators (auth.)

6672, VIDO I. and MALÍK E. II. Intern. Klin. UK, Bratislava. *K niektorým poru-
chám uhl'ohydátového metabolizmu v posthepatitickom syndróme. Changes
in the carbohydrate metabolism after a hepatitis epidemic LÉK. OBZOR 1956, 5/5 (270-276) Graphs 3 Tables 2

Two patients were seen whose symptoms were due to metabolic changes following hepatitis. One patient was so weak, that he was not able to stand on his own feet. His symptoms were mistakenly thought to be due to chronic hepatitis. A more detailed analysis showed a hormonal disturbance, especially insufficiency of the suprarenal glands (glycaemia about 50 mg./100 ml., Na in the blood 240 mg./100 ml., K in the blood 25.7 mg./100 ml.). By giving methylandrostenediol and cortisone the health returned to normal. The 2nd patient was a man who got diabetes as a result of epidemic hepatitis. A detailed analysis of every post-hepatitic syndrome is recommended, because neurasthenic difficulties may be symptoms of chronic hepatitis, as well as disturbances of a metabolic character.

AUTHOR: Vidomenko, Kh. R.

TITLE: Oligocene Geologic History of the Dnepr-Donets Basin
(Geologichna istoriya Dniprovs'ko-Donets'koyi zapadini
v oligotseni)

PERIODICAL: Dopovidi AN UkrSSR, 1956, Nr 6, pp 560-563

ABSTRACT: The Khar'kovskiy stage is subdivided into six cyclic structural sequences. In the central part of the basin the deposits of the Khar'kovskiy stage are sandstones, sands, siltstones, and clays. Variegated and fine-grained glauconitic sands occur along a border of the basin; siltstones are rare; and clays are absent. The thickness of the rocks, from the center of the basin to the edge, ranges from 296.0 to 12.0 m. Tectonic movements, which occurred in the

Card 1/2

15-1957-7-8986

Oligocene Geologic History of the Dnepr-Donets Basin (Cont.)

Oligocene, are indicated by the unconformable relationship between these rocks and the underlying Eocene deposits. An interruption in sediment formation is marked at the boundary between the Khar'kovskiy stage and the Poltavskiy series. Diagnostic fossils are scarce for the Khar'kovskiy stage, and for this reason the author considers it more nearly correct to use the term "Khar'kovskiy series." An outline of the distribution of facies of the Khar'kovskiy stage is given.
