Treatment of sulphur ores with chlorine. K. I. Lamm and H. G. Vetter (Zentralblatt Chem. J., 1934, 11, 67-70). The ore is treated with Cl_2 at 100-150°, when 97% of the S is converted into SO_2 and 2.3% SO_3 ; the process is applicable to ores containing 2.5-3% of S. The S is best recovered by the action of steam on the chlorination product, but about 25% is lost as SO_2 and SO_3 . K. I.

coagulates of arsenic trisulfide and iron oxide. B. G. Zapravator and G. M. Vrublayn. *Kolloid. Zhur.* 10, 230-48 (1948); cf. *C.A.* 24, 699. The vol. V of As_2S_3 ppt. decreases for hours after coagulation. The rate of decrease is greatest for coarsest sols (av. particle size $d = 97 \mu$). If coagulants are compared in the concn. C causing coagulation within 34 hrs., K^+ causes a greater v than Ba^{++} or Al^{+++} , and v increases in the order $Fe(CN)_6^{4-} < SO_4^{--} < NO_3^- < Cl^-$. C usually increases in the order $AlCl_3 < Al(NO_3)_3 < BaCl_2 < Ba(NO_3)_2 < KCl, K_2SO_4 < KNO_3 < K_3Fe(CN)_6 < LiNO_3$. The final vol. V_0 increases when the concn. of added K salt increases and when the concn. of the added Ba or Al salt decreases; thus the mechanism of coagulation is different for uni- and multivalent ions. Near C , multivalent ions yield greater V_0 than univalent ions; this effect is greatest for the finest sol ($d = 26 \mu$). Such sols behave similarly. Coagulation of Fe_2O_3 sols causes formation of 2 liquid layers, and the vol. V_0 of the lower layer decreases more slowly than V of As_2S_3 . On adding increasing amts. of Li_2SO_4 , $MgSO_4$, or K_3PO_4 , V_0 decreases in the beginning but increases during the later part of sedimentation. The V_0 decreases with the concn. of the coagulant increases and the hydration of coagulating ions decreases. Al_2O_3 sols behave similarly to Fe_2O_3 .

The effect on plant growth of substances which lower the oxidation-reduction potential. Artturi I. Virtanen and Sverre Sæviert v. Hansen (Hochem Inst. Helsinki, Finland). *Z. Pflanzenernähr. Düngung u. Bodenb.* 45, 11-22 (1949); cf. *C. I.* 43, 5627. In expts. with cotyledon-free peas in nutrient soln. with nitrate as N source growth is very poor. Addn. of ascorbic acid (I) (100-200 mg per plant in 1 l. of nutrient soln.) gives a growth comparable to normal plants. With $(NH_4)_2SO_4$ as N source on endosperm free wheat, I is ineffective. It is believed that the effect of I on plant growth depends upon its reducing effect on nitrates. Other reducing compds., i.e., glutathione, cysteine, and N_2S_8 , were tested on cotyledon-free peas and showed results comparable with I. It is possible that I functions as a H donor and the -SH compds. reduce the dehydro-I. Thus, the addn. of -SH compds. may result in more effective use of the small amt. of I present in the cotyledon-free embryos. C. K.

Influence of reducing substances on the reduction of nitrate in normal pea plants. Artturi L. Virtanen and Synnøve Sæbø-v. Hausen (Biochem. Inst., Helsinki, Finland) *Skandin. Kemistidelt.* 23B, 61 (1950) (in English); cf. C. I. 44, 6921c. In a normal pea plant grown on nitrate N, considerable accumulation of nitrate occurs unless ascorbic acid be added to the nutrient. This indicates that during germination of the pea reducing substances (ascorbic acid, glutathione, mercaptans) are not formed in optimum amounts, which explains why pea growth is improved by addition of ascorbic acid. Title : Remark on the method of fine crystallization of binary magnesium nitrates of rare earth elements

Periodical : Zhur. anal. khim. 9/5, 299-303, Sep-Oct 1954

Abstract : The effect of the crystallization method of the effectiveness of fractionating cerite-earth mixtures, during fine crystallization of magnesium nitrates, was investigated. The splitting of cerite earth into less soluble Nd, Pr, La and better soluble Sm was quantitatively determined by means of radioactive Eu. Three crystallization methods are described. The third method, consisting of priming the hot solution and chilling during intensive mixing, was found to offer the most effective fractionation. Fine crystallization makes possible rapid elimination of Sm elements from cerite. Two USSR references (1951 and 1952). Tables.

Determination of small quantities of arsenic in organic substances without decomposing them. *N. A. Yanitskaya and S. M. Fomenko (Ukrain. Chem. J., 1960, 6, (264), 278-282).*—The organ is codistilled, and 50 g. of the residue are suspended in water, 10 C.c. of hydrochloric acid and 5 c.c. of 1% cupric chloride are added, and the mixture is boiled for 1 hr. with a copper plate (5 cm. x 2 cm. Bt). The plate is then washed and dissolved in nitric acid, and the solution is neutralized by addition of ammonia, 15-25 drops of dilute hydrochloric acid are added, and it is heated at 100° for 1 hr. The precipitate of cuprous arsenite is washed and dissolved in hydrochloric acid, and 10 drops of 5% sulphurous acid and 2 c.c. of 1% solution in potassium iodide solution are added. The color obtained is compared with that of a standard, and the arsenic content is hence calculated. The method serves for the detection of 0.5 mg. of arsenic per 100 g. of organ, and for the determination, with an error of ±1%, of 2-10 mg. per 100 g. of organ. *Translated by S. L. Kuznetsov.*

TITLE: Measurement of the Ionization of Fast Particles in the Nuclear Emulsion R-NIKFI (Izmereniye ionizatsii bystrykh chastits v yadernoy emul'sii R-NIKFI)

PERIODICAL: Priroda i Tekhnika Eksperimenta, 1958, Nr 2, pp 17-21 (USSR)

ABSTRACT: The ionization produced by protons having energies of 148, 198, 250, 302, 454, 657 and π -mesons having an energy of 300 Mev has been measured and compared with theoretical calculations. The 660 ± 5 Mev proton beam at the United Institute of Nuclear Studies was used for this purpose. The lower energies were obtained by placing aluminium absorbers in the path of the beam and subsequent magnetic analysis. The maximum energy spread at 148 Mev and was 3%. At 657 Mev the energy spread was ± 5 Mev. The plates were 400 microns thick. In order to obtain information on the effect of the conditions of development each plate was cut into three equal pieces and each of the pieces was given a different time in the dry "hot" stage. The actual times were 25 minutes (under-developed), 40 minutes (normal) and 55 minutes (over-developed). It was found that for energies greater than 300 Mev the experimental data agree

Card 1/2

SOV/170-53-2-3/77

Measurement of the Ionisation of Fast Particles in the Nuclear Emulsion R-NIKFI.

well with theoretical calculations if the measurements are carried out with an accuracy of a few percent. In this region the grain density does not differ from true relative ionisation by more than 2%. For energies less than 300 Mev a correction is necessary for the effect of overlapping of grains. A method of applying this correction is described. The correction is carried out in terms of a parameter d which plays the role of an effective grain size. The following persons are thanked for their interest and help: M.I.Podgoretskiy, L.I.Fedcova, K.I.Zhabina and D.V.Makarova. There are 5 tables and 1 Soviet, 2 English references.

TITLE: Production of a $\bar{\Sigma}^-$ -Hyperon¹⁹ by Negative π^- -Mesons With a
Momentum of 8.3 Bev/c

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1960,
Vol. 38, No. 4, pp. 1356 - 1359

TEXT: In the present "Letter to the Editor", the authors give a detailed
report on the case of a $\bar{\Sigma}^-$ -production and decay discovered by them for
the first time among 40,000 bubble-chamber photographs. The chamber hap-
pened to be in a 13,700-oe magnetic field. The photograph concerned is
represented as well as the track scheme. The tracks are numbered, and
the individual stars are denoted as "point A, B, O, ..". The exact data
of the tracks and stars, respectively, are given in tables (Table 1:
"Kinematics at point A"; Table 2: "Kinematics at point B"; Table 3: ✓

"Kinematics at point O"; and Table 4: "Kinematics at points O' and O" "). The individual tracks are identified, and the charges and momenta (measured and calculated) of the particles, the kinetic and mass energies, and the total energy are given. For the stars B and O also the energy balance is given. For B, the following is considered to be the most probable reaction: $\bar{n} + C \rightarrow He^4 + 4p + 3n + \pi^+ + \pi^- + n\pi^0$. For the primary star (Tables 3 and 4)² the following reaction is assumed:
 $\pi^- + C \rightarrow \bar{\Sigma}^- + K^0 + \bar{K}^0 + K^- + p + \pi^+ + \pi^- + \text{recoil nucleus}$. The lifetime of the $\bar{\Sigma}^-$ -hyperon was calculated to be $(1.18 \pm 0.07) \cdot 10^{-10}$ sec. G.A. Blinov and S. Z. Otvinovskiy are mentioned. There are 2 figures, 4 tables, and 4 references: 3 Soviet and 1 US. X

TITLE: Channel for Antiprotons¹⁹ With a Momentum of 2.8 Bev/c

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, 1960,
Vol. 38, No. 2, pp. 445-448

TEXT: The authors of the present paper describe a channel built for the investigation of the interaction of antiprotons in a cloud chamber. Antiprotons were produced by 9-Bev protons in a target. Fig. 1 is a schematic representation of the channel described in the following. The antiprotons were identified from their velocity ($\beta = 0.95$) by means of three Cherenkov counters, each of which was provided with two photomultipliers of the type $\phi 3\gamma-33$ (FEU-33) whose efficiencies are specified in Table 1. The efficiencies attained with different coincidence combinations are given in Tables 2 and 3. Fig. 2 shows a block diagram of the electronic

system, and respective data are supplied in Table 4. The efficiency of the scheme described with respect to antiprotons is found to be 60-40%. Some tests are briefly described next. By the system discussed here, the authors determined the ratio of the number of \bar{p} with momenta of (2.8±15) Bev/c to the number of all remaining particles (which were chiefly π^- -mesons) from the beryllium target (36g/cm²) under the angles 0 and 7°, and from a copper target (~180 g/cm²) under 7° with respect to the primary proton beam (8.1 - 8.9 Bev). At an intensity of 10⁹p of the inner beam, an average of 1 \bar{p} was recorded within four minutes. Results:

Angle	target	proton beam intensity	particle number in the channel	relative number of anti-protons in the beam
0°	Be	10 ⁹	1000	(1.03±0.13).10 ⁻⁴
7°	Be	10 ⁹	~700	(1.37±0.18).10 ⁻⁴
7°	Cu	10 ⁹	~700	(2.42±0.53).10 ⁻⁴

The number of particles recorded in the channel agrees with data concern-

ing 9-Bev proton interactions in emulsions (Ref. 4). The increase in the relative number of antiprotons in the transition from 0 to 7° in the laboratory system agrees with predictions made on the strength of the statistical theory. By considering pion absorption ($\sigma_t \sim 30$ mb) and antiproton absorption ($\sigma_t \sim 60$ mb) as well as the attenuation of the beam of primary protons ($\sigma_{in} \sim 30$ mb), the ratio of the differential production cross sections of \bar{p} and π^- -mesons with 2.8 Bev/c under 0° in the laboratory system is found to be

$$\frac{d^2\sigma_{\bar{p}}}{d\Omega dp} / \frac{d^2\sigma_{\pi}}{d\Omega dp} \approx 1.5 \cdot 10^{-4} .$$

TITLE:

Production of Ξ^- hyperons by the use of π^- mesons with a momentum of 7000 Mev/c and 8000 Mev/c

PERIODICAL:

Wu Li Hsueh Pao, v. 17, no. 5, 1961, 205-213

TEXT:

The productive cross section σ ($\sigma = 3.6 \pm 2.5 \mu\sigma/N$ at 6800 Mev/c, $\sigma = 10.6 \pm 4.4 \mu\sigma/N$ at 8000 Mev/c), mass M_{Ξ^-} ($M_{\Xi^-} = 1317.0 \pm 2.2$ Mev), and lifetime τ_0 ($\tau_0 = 3.5 \pm 3.4 \times 10^{-10}$ sec) of Ξ^- hyperson were determined by the use of π^- mesons having momentums of 6800 Mev/c and 8000 Mev/c. In early investigations Ξ^- hyperons

Card 1/4

C/026/61/017/005/001/006
F050/F004Production of Ξ^- hyperons by ...

were found by experiments with cosmic rays. A butane bubble chamber 24 liters in volume in a permanent magnetic field of 13700 gauss was used. The chamber was irradiated by a bundle of mesons with momentums of 7000 Mev/c and 8000 Mev/c. The result was 27,000 and 75,000 negatives obtained recording momentums of 6800 ± 600 Mev/c and 8000 Mev/c of π^- mesons. A three-dimensions amplifier and projector were used to trace the negatives twice and some negatives were traced three times. In the tracing process those events which could be classified with Ξ^- hyperon decay scheme $A \rightarrow V^0 + B$, $V^0 \rightarrow C + D$, by appearance were selected. The following standards were applied in the determination of Ξ^- hyperons: (1) V^0 must coincide with kinematics of the decay scheme $\Lambda^0 \rightarrow p + \pi^-$, (2) The refraction point must be within the Λ^0 decay plane. The vertical momentum of π^- meson and proton p, which came from Λ^0 decay relative to the projecting direction of Λ^0 , must be in equilibrium. (3) The Λ^0 decay particles should lie on the plane formed by particles A and B. (4) At the refraction point, the vertical momentum of particles Λ^0 and B particle must be in equilibrium. (5) The events must satisfy kinematics of Ξ^- hyperon decay scheme

Card 2/4

C/026/61/017/005/001/006
F050/F004Production of Ξ^- hyperons by ...

Among all the events there were 11 events which satisfied all 5 standards. Three events coincided well with the kinematics of Ξ^- decay and have been classified with Ξ^- hyperon. Of all Ξ^- hyperons, one was obtained by the bundle of π^- mesons with 6800 Mev/c and then were obtained by the bundle of π^- mesons with 8000 Mev/c. The results of this experiment are listed in four tables: (1) Table 1 lists data of defined Ξ^- . All these data were average values which were obtained by using a microscope to measure two — four times independently. It also lists the decay energy Q and lifetime of all Ξ^- hyperons found in their own coordinate system. (2) Table 2 lists all data concerning the primary stars. These stars have been analyzed as the source of Ξ^- hyperons. (3) Table 3 lists the momentum p^* in a $\pi^- N$ mass center system, vertical momentum p^\perp , and projecting angle θ^* of Ξ^- hyperons (suppose Ξ^- hyperons were produced by the impact of π^- mesons to free nuclei). The average vertical momentum ($p_{\Xi^-}^\perp$) of Ξ^- hyperon is equal to 318 \pm 35 Bev. This value is approximate to the vertical momentum of proton and Λ hyperon. This table also lists the characteristics of the following angles: (a) θ_Λ^* is the projecting angle of Λ^0 which is projected out from Ξ^- hyperon decay process under its equilibrium

Card 3/4

Production of Ξ^- hyperons by ...

C/026/61/017/005/001/006
F050/F004

system. (b) θ_p^* is the projecting angle of p which was projected out from the decay process in its equilibrium system. (c) $\omega_{\Xi-\Lambda^0}$ is the intersection angle between Ξ^- and Λ^0 decay planes. In the distribution of θ_p^* and $\omega_{\Xi-\Lambda^0}$, no asymmetry was observed. (4) Table 4 lists the events which seems to be Ξ^- . Among these events, four were in the same plane and fourteen were in different planes. Most of these events in the same plane were induced by $\pi^+\pi^-$ mesons; the others in different plane events may have been induced by π^+ , π^- or K^- mesons. Thanks are extended to V. I. (Wei Ke Shih Lai Erh), I. V. (Chi Wei Lo), L. P. (Chi Lo Wei Yeh Fu), N. I. (Pa Pu La Fe), K. V. (Chi Ho Lo Fu), and L. N. (Chll Lao Yeh Fu). There are 3 figures and 4 tables. The English-language references read as follows: C. Franzinetti and G. Morpurgo. Suppl. Nuovo Cim. 6 (1957), 565; W. B. Fowler et al. Nuovo Cim. 11 (1959), 428.

$A \rightarrow V^0 + B, V^0 \rightarrow C + D$ as well as all singly-pronged stars from the vertex of which a V^0 particle departed. Altogether, 90 events were chosen; they were measured by means of УММ-21 (UIM-21) microscopes, and the results were evaluated by means of an electronic computer of the type "Ural"; 11 events of a Ξ^- -decay ($\Xi^- \rightarrow p^0 + \pi^- + 65 \text{ Mev}$) were identified according to rigorous criteria. The angular and momentum characteristics of the identified Ξ^- hyperons are given in Table 1. The events nos. 171-218 and nos. 19-179 are schematically shown in Figs. 1 and 2, respectively. The Table gives the data concerning the decay energy Q and the lifetime (until the decay) of the Ξ^- hyperons. The mean value of Q from the 11 Ξ^- decay events was $Q = 61.9 \pm 2.2 \text{ Mev}$ from which the hyperon mass $M_{\Xi^-} = 1317.0 \pm 2.2 \text{ Mev}$ was calculated. The mean lifetime was $\tau_0 = (3.5^{+3.4}_{-1.2}) \cdot 10^{-10} \text{ sec}$. The mean free path of the π^- mesons in Ξ^- -hyperon formation in propane was $l = (2.02^{+2.86}_{-0.84}) \text{ cm}$ for a momentum of 6.8 Bev/c and $l = (0.68^{+0.29}_{-0.20}) \text{ cm}$ for $\sim 8 \text{ Bev/c}$. Assuming that the Ξ^- -hyperon production cross section in nu-

TEXT: 60000 photographs were examined of the interaction of π^- -mesons of
7 - 8 Bev/c with protons in a 24-liter propane bubble chamber in a
permanent magnetic field of 13,700 oe. Method and apparatus have already
been described (Wang Kang-oh'ang, M. I. Solov'yev, Yu. M. Shkolin. PTE, 1,
41, 1959; M. I. Solov'yev, Proc. of the 1960 Ann. Int. Conf. on High
Energy Physics at Rochester, p. 388; Wang Kang-oh'ang et al. ZhETF, 39,
1854, 1960). The Λ -hyperons were unpolarized during their production.
This follows from the fact that there is no asymmetry in the angular dis-
tributions of the protons from the decay of the Λ -hyperons relative to
the hyperon momentum. The angular distributions of the Λ -hyperon produc-

TITLE: Investigation of Λ -hyperon and K^0 -meson production
processes in π^+p interactions at 7-8 Bev

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 44,
no. 2, 1963, 431-443

TEXT: The c.m.s. momentum and angular distributions determined for the
 Λ and K^0 particles produced in πp interactions are given and discussed.
The measurements were made using a 24-liter propane bubble chamber in a
field of 13,700 oe. The total momentum spectrum of the Λ -hyperons
produced in the reactions

Card 1/7

Investigation of Λ -hyperon ...

S/056/63/044/002/007/065
B102/B186

are shown in Fig. 1, compared with theoretical results. As it may be seen the statistical theory describes the experimental curve very well if the isobars and, the cases with $p_{\perp} - p = \Delta < 700$ Mev are neglected.

$\Delta < 700$ Mev corresponds to $\sim 30\%$ of all Λ , these being produced in peripheral interactions. The Λ angular distribution has a distinct backward peak ($\bar{n}_{\Lambda} / \hat{n}_{\Lambda} = 0.18 \pm 0.02$). With increasing multiplicity n_g the agreement between experiment and statistical theory improves. The Λ angular distribution and the distribution with respect to p_{\perp} is virtually independent of n_g . The overall mean of the transverse momentum is 383 ± 12 Mev/c; for $\Delta < 700$ Mev, $\bar{p}_{\Lambda_{\perp}} = 295 \pm 14$ Mev/c and for $\Delta \geq 700$ Mev, $\bar{p}_{\Lambda_{\perp}} = 432 \pm 18$ Mev/c. For the $K^0(\bar{K}^0)$ mesons produced in the reactions

Card 2/7

S/056/63/044/002/007/065
B102/B186

Investigation of Λ -hyperon ...

the total momentum spectrum measured (Fig. 4) is weaker than that calculated according to the statistical theory. The angular distribution (Fig. 5) has, besides the isotropic part, a forward peak ($\frac{n_{K^0}^+}{n_{K^0}^-} = 1.61 \pm 0.15$). The forward-backward ratio decreases with increasing n_s . For the charged pions arising in Λ -production events the momentum distributions are, for $p_\pi^* \geq 400$ Mev/c, well described by the statistical theory without taking the isobars into account; for $p_\pi^* < 400$ Mev/c it is higher than that obtained from theory. The angular distributions for $n_s = 2, 4, 6$ are characterized by

Card 3/7

Investigation of Λ -hyperon ...S/056/63/044/002/007/065
B102/B186

$$\bar{n}_{\pi^+}/\bar{n}_{\pi^-} = 1.10 \pm 0.12, \quad \bar{n}_{\pi^-}/\bar{n}_{\pi^+} = 1.40 \pm 0.13.$$

The mean number of π^0 mesons produced per π^-p interaction with Λ production is 1.23 ± 0.14 . The angular distribution of π^- arising in stars with K^0 production has a flat forward maximum ($\bar{n}_{\pi^-}/\bar{n}_{\pi^+} = 1.10 \pm 0.10$). The mean number of charged particles produced together with Λ is $n_s = 2.22 \pm 0.13$ which agrees closely with the statistical theory without the isobars. The main part of Λ and K^0 is produced in two-pronged stars. The admixture of $K^0 \Sigma^\pm$ pairs amounts to less than 20% of the number of $K^0 K^- + K^0 K^+$ pairs. The momentum distribution of charged pions from π^-p interactions with Λ -hyperon production are characterized by $\bar{p}_{\pi^+}^* = 425 \pm 16$ Mev/c and $\bar{p}_{\pi^-}^* = 444 \pm 15$ Mev/c. From a comparison of these angular distributions it is concluded that processes involving ΛK or $K\bar{K}$ pair production are more central than the usual processes of multiple pion production. If one divides the π^-p interactions with strange particle production into head-on

Card 4/7

Investigation of Λ -hyperon ...

S/056/63/044/002/007/065
B102/B106

and peripheral collisions one can say that those involving $K\bar{K}$ pair production are rather of the head-on type than those with ΛK pair production. There are 15 figures and 2 tables.

TITLE: A study of the ¹⁹properties of neutral pions produced with strange particles in negative pion proton and negative pion carbon interactions.

SOURCE: Zhurnal eksper. i teoret. fiziki, v. 44, no. 5, 1963, 1474-1480

TOPIC TAGS: Neutral pions, strange particle interactions

ABSTRACT: An earlier investigation on the production of strange particles by 7-8 Bev negative pions on hydrogen and carbon was continued with a 24 - liter propane bubble chamber. The properties of the neutral pions inferred from the photons accompanying the LAMBDA hyperon and neutral kaon production are given and are compared with the properties of the pions (positive and negative) emitted in LAMBDA and neutral-kaon production processes. In calculating the total number of photons, corrections were introduced for the loss of photons

TITLE: Antilambda hyperon¹⁹ production by 7-8 GeV negative pions on hydrogen

SOURCE: Zhur. eksper. i teoret. fiz., v. 45, no. 2, 1963, 88-89

TOPIC TAGS: hyperon production, antilambda, negative pion decay, cross section

ABSTRACT: The production and decay of $\bar{\Lambda}$ hyperons by 7--8 BeV negative pions are reported, on the basis of 42 V^0 events in which the momentum of the negative particle from the decay was greater than the momentum of the positive particle and the transverse momentum of the decay products was less than or equal to 100 MeV. Selection of the $\bar{\Lambda}$ hyperons was by kinematic criteria, measurement of ionization, and determination of the δ -electron energy. The cross section for the production of $\bar{\Lambda}$ hyperons is found not to differ much from the cross section of Λ production, or about 3 μ b. Orig. art. has 1 figure and 1 table.

(ZhETF v. 40, 464, 1961) from π^-p interactions at the same pion momentum. A 24-liter propane bubble chamber in a constant field of 13,700 Oe was used in accordance with a procedure described before (ZhETF, v. 38, 426, 1960). The purpose of the experiment was to estimate the fraction of the secondary interactions. An estimate was made for the first time of the fraction of strange particles produced in the secondary processes. The momentum spectrum of the Λ hyperons (in the pion-nucleon center of mass system) was compared with the spectrum for the π^-p interactions. The following distribution of events over the reaction channels was obtained

	$\Upsilon^0 K^0$	$\Upsilon^0 K^+$	$K^0 \bar{K}^0$	$K^0 K^- + K^+ \bar{K}^0$	$\Sigma^\pm K^0$	$\Upsilon^0 \Upsilon^0 K K$
Number of events	427±69	223±81	147±52	323±127	80±31(3)	4(1)
Cross section, mb	4,8±0,8	2,5±0,9	1,7±0,6	3,6±1,4	0,8±0,4	0,04

and the cross section for each interaction event with the carbon was calculated to be 0.0113 mb. This yielded the following cross

ACCESSION NR: AP4037568

sections

$$\sigma(\pi^0 \Lambda^0) = 7,3 \pm 1,2 \quad \text{and} \quad \sigma(K^0 \bar{\Lambda}) = 5,3 \pm 1,5$$

The good agreement between the calculated and experimental values of the spectra of the Λ hyperons and K^0 mesons gives grounds for assuming that the cascade model holds true for these phenomena. It also is concluded that the previously observed hard part of the momentum spectrum of the Λ hyperons in the pion-nucleon center of mass system in πp interactions is due to an admixture of carbon events, and that the role of the secondary processes which lead to the production of strange particles is quite appreciable even on the carbon nucleus. "The authors are grateful to I. Klugov and M. Shneyeberger for help at the beginning of the work, to V. S. Barashenkov, I. V. Chuvilo, and M. I. Podgoretskiy for discussion and valuable remarks, to Ye. P. Zhidkov, G. A. Ososkov, and K. N. Danilova for help with the calculations, and to the laboratory group for the measurements." Orig.

TITLE: Pion resonances produced simultaneously with strange particles in negative pion proton interactions at 7.5 GeV/c

SOURCE: Zh. eksper. i teor. fiz., v. 46, no. 6, 1964, 1967-1978

TOPIC TAGS: pion, negative pi meson, strange particle, resonance scattering, omega meson, proton reaction

ABSTRACT: Continuing a series of earlier research on the generation of strange particles and pions in a beam of 7.5 GeV/c negative pions (ZhETF v. 43, 815, 1962; v. 44, 431 and 1474, 1963; Proc. 1960 Rochester Conf., 1961, p. 388), the authors investigated with the aid of a 24-liter propane bubble chamber the pion resonances produced simul-

Card 1/3

ACCESSION NR: AP4042554

taneously with strange particles. Pion resonances produced in interactions of the type

were investigated (m -- number of pions). Simultaneous production of ρ^0 mesons and ΛK pairs was observed in events characterized by a charged particle multiplicity $n_s = 4$ and having cross sections of 20 ± 8 microbarns. Cross sections for the production of ω and η resonances are presented. It is concluded that the four-pion effective
