TITLE: De-sulphurisation of Benzole with Complex Compounds of Aluminium Chloride with Hydrocarbons. (Obesserivaniye benzola kompleksnymi soyedineniyami khloristogo alyuminiya s ulevodorodami)

PERIODICAL: Koks i Khimiya, 1957, No.1, pp. 53 - 54 (USSR)

ABSTRACT: The use of aluminium chloride complex with hydro-carbons left after the synthesis of ethylbenzene for the de-sulphurisation of benzole was investigated. Experiments were carried out in a reactor with a reflux condenser, thermometer and a stirrer. The investigating technique was as follows: a mixture of benzole and the complex in a proportion of 1:15 was placed in the reactor, heated to a required temperature (24 °, 50 ° and 70 ° C) and stirred for a required time. Then after settling (15 min) of the catalyst, the top layer of purified benzene was sucked off, washed with water, dried and distilled. The determination of sulphur on bromine numbers of raw and treated benzene were carried out. The influence of the duration of treatment on the degree of de-sulphurisation is given in Fig.1 and the dependence of the efficiency of purification on the temperature and volume of the benzene treated with the

Card 1/2 same catalyst - in Fig. 2. The results obtained indicated that

68-1-16/21

De-sulphurisation of Benzole with Complex Compounds of Aluminium Chloride with hydro-carbons.

the efficiency of purification of benzole with aluminium chloride solutions (in the form of complex compounds with hydro-carbons) is as high as with crystalline aluminium chloride. The loss of aluminium chloride when treating 90 volumes of benzole with 1 volume of the catalyst was about 0.4%. As the amount of aluminium chloride left in the complex after the synthesis of ethylbenzene in the majority of cases is sufficient for the purification of fresh benzole required for the reaction, the use of crystalline aluminium chloride can be more efficient.

TITLE:

On the Influence of Some Driers on the Rate of the Oxidation of Ethyl Benzene and Isopropyl Benzene With Oxygen (O vliyanii nekotorykh vysushivayushchikh veshchestv na skorost' okisleniya etilbenzola i izopropilbenzola kislородom)

PERIODICAL:

Khimicheskaya promyshlennost', 1958, Nr 7, pp 413 - 416 (USSR)

ABSTRACT:

The experiments were carried out with an arrangement consisting of four 1 l containers. Some little pieces of the drier are put into each of the vessels (metallic sodium, sodium and potassium hydroxide, or calcined calcium chloride). The control tests were carried out with a similar arrangement with ethyl benzene of the same quality, however, instead of air (or oxygen) nitrogen was conducted through the system. The experiments with ethyl benzene demonstrated that it relatively easily oxidizes, and that its oxidizability is mainly increased by KOH and metallic sodium as well as an increase in temperature. It is recommended to blow nitrogen through the apparatus as well as onto those liquid faces that come into contact with the air when heating or boiling ethyl benzene. Calcium chloride or sodium hydroxide should

Card 1/2

On the Influence of Some Driers on the Rate of the
Oxidation of Ethyl Benzene and Isopropyl Benzene
With Oxygen

SOV/64-58-7-7/18

be used for drying. The experiments with isopropyl benzene yielded the same results as those with ethyl benzene. The presence of KOH effected also in this case a more intense oxidation at a contact with atmospheric oxygen. There are 2 figures, 2 tables, and 4 references, 3 of which are Soviet.

TITLE: Moisture resistance and chemical stability of unsaturated polyester resins modified with colophony

SOURCE: Plasticheskiye massy, no. 9, 1966, 40-42

TOPIC TAGS: solid mechanical property, polyester plastic, synthetic material, physical chemistry property, stability constant

ABSTRACT: Moisture resistance and oxidation stability of two commercial resins modified with colophony, resin PN-10-^b a copolymer of an unsaturated ester with styrene and resin TGM-3-^b (a copolymer of an unsaturated ester and polyacrylate) and some glass laminates based on these two resins were investigated. The physical properties of the colophony-modified resins are tabulated. The tensile strength of the colophony-modified resins and the glass-laminates based on them was practically unaffected after holding in water or 25%-sulfuric acid for 7-360 days. In general, the addition of colophony was found to be beneficial with respect to water resistance and chemical stability of the unsaturated polyester resins. Orig. art. has: 1 figure and 3 tables.

...expressions of the form $\sum_{j=1}^n A_j x^j$ satisfies the equation $\sum_{j=1}^n A_j x^j = 0$, A_j being constants. Operations with such functions, in particular, integration and differentiation, are defined. A generalized Cauchy formula is introduced. The components of the functions satisfy systems of linear partial differential equations. In particular, it is possible to obtain solutions of the Laplace and biharmonic equations; the author obtains general formulas for the representation of their solutions. These formulas can be used for the solution of boundary value problems. The reviewer remarks that since the question of uniqueness of the representation of functions should be clarified.

3801. Thermomagnetic and Thermoelastic Phenomena in Ferromagnetics. D. Volkov. *J. of Exp. and Theor. Physics, U.S.S.R.* 9. 4. pp. 444-450, 1959. *In Russian.*—The author describes measurements on the Thomson-Nernst effect (change of thermoelectric force in magnetic field) and the thermoelastic effect (change of thermoelectric force with stress) for weak tensions in iron and nickel wires. The combined effect of a field and a weak tension was also measured. In each case the thermal e.m.f. was measured against Cu. The results were found to agree with Akulov's theory of even-order effects. D. S.

REMARK: This volume is intended for geographers, ecologists, geologists, and
photogrammetrists.

CONTENTS: This collection of 23 articles contains studies of the earth's surface,
structure, and ecological formations by means of aerial photography. The
authors discuss the principles, methods and techniques used in aerial surveying
to determine such factors as the petrographic composition of the soil through
the microscope, the spectral brightness of surfaces, the geological structure
of underwater structures through recorded photographic images, the geological analy-
sis of surface plant coverings, the trends and characteristics of recent ter-
restrial movements through the study of surface features traced photographically
under microscope.

ON THE THERMOMAGNETIC AND THERMOELASTIC PHENOMENA IN FERROMAGNETIC METALS.

m

On the Thermomagnetic and Thermoelastic Phenomena in Ferromagnetic Metals. [Nickel and Iron.] D. I. Volkov (*Zhur. Eksp. i Teor. Fiziki (J. Exper. Theoret. Physics)*, 1939, 9, 444-450; *Chem. Zentr.*, 1940, 111, (11), 3157).—[In Russian.] Cf. *ibid.*, 1939, 9, 798; *Met. Abs.*, 1943, 10, 341.

V. investigated the Thomson-Nernst thermomagnetic effect and the thermoelastic effect in nickel and iron in weak magnetic fields. The experiments showed a rapid increase of the thermo-e.m.f. with a gradual transition to saturation, which occurs at the same value of H as the magnetic saturation. The change of the thermoelectric properties is thus limited in relation to the anisotropy by the orientating effect of the field in the region of spontaneous magnetization. The thermo-e.m.f. of nickel increases, and that of iron decreases, with the increase of tensile stress.

Effect of Elastic and Residual Deformations on the Galvanic Effect of Ferromagnetic Materials (Nickel). K. P. Belov and D. I. Volkov (*Zhur. Tekhnich. Fiziki (J. Tech. Physics)*, 1939, 9, 1529-1539; *Chem. Zentr.*, 1940, 111, (1), 2132).--(In Russian.) In plastic deformation, zones of tensile and of compressive stresses in the metal can be postulated, the magnitude, number, and direction of which depend on the nature of the deformation. B. and V. assume a model of distribution of internal stresses in a nickel wire after plastic deformation, in which tensile and compressive zones alternate periodically in the cross-section. Corresponding to the stress directions, the magnetization vectors lie parallel and vertical to the axis of the wire, this explaining the decrease of galvanomagnetic effect by 25% in drawn nickel compared with annealed soft nickel. Galvanometric and similar effects may serve in general as sensitive indicators of the internal stress distribution in ferromagnetic metals.

Measuring results for ferromagnetic materials are reported for magnetostriction and magnetic field strength obtained on annealed specimens of a Fe-Co alloy (bands 200 x 2 x 0.2 mm). The bridge was operated at 2 000 c/s, the measuring elements had a constantan base and 241-ohm resistance. The results were checked by d.c. bridge tests with the same strain gauges, and full agreement was found. Good agreement also with results obtained with a mirror galvanometer. E. F. KRALY

Magnetostrictive hysteresis of high-coercive steels. 1).
 I. Volkoy (M. V. Lomonosov State Univ., Moscow) • Doklady Akad. Nauk S.S.S.R. 73, 117-119 (1950). - Magnetostriction, λ , was measured by a wire tensometer on Vicalloy (Fe-38, Co 52, V 10%) strips that had been given coercive forces, H_c , ranging from 48 to 310 oersteds by cold working and then annealing at 800 to 600°. For $H_c = 310$, the variation of λ with magnetization, I , below I_c was $\lambda = kI^2$; for $H_c = 48$, $\lambda = k(I^2 - I_c^2)$, where $I_c \leq I < I_s$ and I_s is satn. magnetization. This difference is due to the displacement of domain boundaries in the low- H_c alloy in addn. to domain rotation, which also occurs in the high- H_c alloy. Hysteresis loops, λ vs. H , were detd. for alloys with $H_c = 177$ and $H_c = 48$. The loop area was greater the greater H_c and I_c , the residual magnetization. Residual magnetostriction, λ_r , was small compared to λ_{max} for $H_c = 48$ and was large for $H_c = 177$. When H_{max} was less than 150, λ was about zero. Above this value of H_{max} , λ increased rapidly at first and then leveled off at the value for I_s . For $H > H_c$, λ was proportional to the I^2 . For $H < H_c$, this proportionality disappeared since λ was almost zero while I_c was fairly large. This fact also showed that domain boundary movement occurred. Good agreement was found between the data and Weiss-Kondorskil theory. A. G. Guy

The magnetostriction of ferromagnetic alloy in parallel and transverse fields. D. I. Volkov. *Uchenye Zapiski Mosk. Gosudarst. Univ. Ser. Fiziko-Matematicheskie Nauki* No. 162, Fizika No. 6, 33-50 (1952); cf. C.A. 49, 20785. The magnetostriction of polycryst. ferromagnetic alloys was calculated for a parallel and a transverse field at satn.; consideration was given to all terms to the 6th power in the expression for the anisotropy tensor in order to det. the accuracy of the 2nd rule of Akulov's theory of even effects (Akulov, *Ferromagnetism*, 1939). This theory which states that in the absence of the para-process, the parallel effect is twice as great as, and of opposite sign to the perpendicular effect. Results show that Ni alloys follow this rule very well. The Mn alloys do not follow the rule, and reasons for this are discussed.

Title : Temperature Dependence of Magnetostriction of Ferromagnetic Alloys.

Orig Pub : Vestn. Mosk. un-ta, 1956, No 2, 21-28

Abstract : An experimental study was made of the temperature dependence of the magnetostriction of saturation λ_s of ferromagnetic alloys with a nickel base (Ni-Cu, Ni-Co, Ni-Mn and a Ni-Fe alloy with 45% nickel) in the temperature region close to the Curie point. It was established that in this temperature region the variation of λ_s with T is linear in character, and this is in accordance with the theory of the temperature dependence of even Akulov effects. For Ni-Co al-

Abstract : loys (2.4 and 6% Co) and the Ni-Fe alloy (45% Ni) this linear dependence of λ_s on T is observed in a greater range of temperatures than for Ni-Cu and Ni-Mn. It is noted that on the $\lambda_s(T)$ curves of the Ni-Cu and Ni-Mn alloys (3.7 and 8.5 atomic percent of manganese), in the direct vicinity of the Curie point (θ), there appear clearly pronounced asymptotic "tails" which vanish at $T_k > \theta$. For the case of Ni-Cu alloys, the authors establish the dependence of T_k on the composition of the alloy. The authors propose that such "tails" on the $\lambda_s(T)$ curves are due to micro-irregularities in the composition and to the appearance of magnetic ordering at close distance. A study of the temperature dependence of λ_s for Ni-Co alloys (29 and 30.5% Ni) which have an allotropic transformation, has shown that at the transfor-

PERIODICAL: Fizika Metallov i Metallovedeniye, 1957, Vol.5, No.1, pp. 168-169 (USSR)

ABSTRACT: The temperature dependence of the paramagnetic susceptibility of ferromagnetic alloys was investigated in the temperature range from the ferromagnetic Curie point to 1200°C in vacuum by means of the Faraday-Sacksmith method for the binary alloys Ni-Cu, Ni-Al, Ni-Si, Ni-Sn, Ni-Cr and Ni-Mo in which the concentration of the non-ferromagnetic component was varied within wide limits. The investigations have shown that in the high temperature range the paramagnetic susceptibility of the studied alloys can be satisfactorily described by the relation:

$$\chi = \chi_k + \chi_T \quad (1)$$

TITLE: Temperature Dependence of the
Paramagnetic Susceptibility of Alloys on a Nickel-
basis (Temperaturnaya zavisimost' paramagnitnoy
vospriimchivosti splavov na osnove nikelya).

PERIODICAL: Izvestiya AN SSSR Seriya Fizicheskaya, 1957, Vol. 21,
Nr 8, pp. 1111-1115 (USSR)

ABSTRACT: As an introductory remark it is maintained here that
this field of research has not been fully explored.
From a theoretical point of view it is generally
assumed, that the paramagnetic susceptibility of ferro-
magnetic metals in the range of temperatures above the
ferromagnetic Curie-point $T > \theta_f$ is caused by the inner
electrons. Whereas the role of the outer electrons is
not touched at all. Under certain circumstances, how-
ever, the consideration of the effect of s-electrons
might be of great importance in the range of temperatures
above the Curie-point, because here the peculiarities
of the temperature dependence of the paramagnetic
susceptibility of alloys containing non-ferromagnetic

CARD 1/3

Temperature Dependence of the Paramagnetic Susceptibility of Alloys on a Nickelbasis 48-8-10/25

elements with differing valence must be taken into consideration. This problem was investigated in this paper. Experimental research was executed on pure nickel and its alloys with non-ferromagnetic components: Ni-Cu, Ni-Zn, Ni-Al, Ni-Si, Ni-Mo and Ni-Cr in the temperature range from the Curiepoint up to 1200°C. The method by Faraday-Sucksmith was employed for the measurement of the paramagnetic susceptibility, the investigations being conducted in vacuum up to 1200°C. The conclusions drawn here are such, that the paramagnetic susceptibility of ferromagnetic alloys does not follow the law by Curie-Weiss, at high temperatures, but the generall law

$$X = X_k + \frac{C}{T - \theta_p}$$

, C denoting the Curie-Weiss constant,

θ_p the parametric Curie point, X_k a X independent of temperature. Further research furnished, that the paramagnetic susceptibility is largely dependent on the

CARD 2/3

Temperature Dependence of the Paramagnetic Susceptibility of Alloys on a Nickelbasis 48-8-10/25

strength of the magnetic field at temperatures near the Curie point, and that with an increase of the concentration of the non-ferromagnetic components in the nickel alloy the values of the coefficients dependent upon temperature and the composition of the alloy decrease. Near the Curie point the parameter varies with a linear relation and drops to zero at the Curie point. There are 8 figures and 7 references, 1 of which is Slavic.

TITLE: Hall effect in nickel alloys

SOURCE: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 48, no. 1, 1965, 65-68

TOPIC TAGS: nickel alloy, electric resistivity, magnetoresistance, temperature dependence, Hall constant, conduction electron, electron scattering

ABSTRACT: Unlike in earlier investigations, the authors analyze simultaneously the data on the dependence of the Hall constant R_S on both the electric resistivity ρ and the magnetic part of the resistivity (ρ_m), as well as on the spontaneous magnetization in Ni-Mo alloys (up to 5 at.% Mo) and Ni-Si alloys (up to 3 at.% Si) in the interval from room temperature to well above the Curie point. The purpose of the investigation was to check on the validity of the frequently quoted theoretical relation $R_S = a\rho + b\rho^2$. The theoretical relations between the Hall constant and the electric resistivity and the magnetoresistivity are confirmed experimentally. The experimental dependence of R_S on the temperature is found to

Card 1/2

L 28757-65

be $R_s = b_0 + b_1T + b_2T^2$. It is concluded that contributions to the anomalous Hall effect are made by both the impurity-phonon mechanism of conduction-electron scattering and by scattering from magnetic inhomogeneities. "We thank Professor Ye. I. Kondorskiy for participating in the evaluation of the results." (Orig. art. has: 3 figures and 6 formulas.

TITLE: The Hall Effect in Ferromagnetics

PERIODICAL: Vestnik Moskovskogo universiteta. Seriya 3, fizika, astronomiya, 1960, No. 4, pp. 18-20

TEXT: The author of the present paper studied the temperature dependence of the Hall effect in ferromagnetic substances. If also paramagnetic processes occur in these substances, then the Hall effect at temperatures below the ferromagnetic Curie point θ_f is given by the following

equation: $E = R_0 H + RI + R_i I_i$ (2) (E = Hall emf, referred to the units of current density and the electrode spacing; R = Hall constant in the technical magnetization I; R_0 = "classical" Hall constant; H = magnetic field strength; I_i = magnetization depending on the para-process; R_i = Hall constant corresponding to the para-process). At temperatures in the immediate vicinity of the Curie point ($T \lesssim \theta_f$) the term RI can be

Card 1/4

83928

The Hall Effect in Ferromagnetics

S/188/60/000/004/002/014
B005/B060

neglected in equation (2). However, it is more appropriate not to determine the Hall emf in this temperature range as a function of I_1 , but of H , this being easily feasible with the aid of an equation theoretically derived by V. L. Ginzburg (Ref. 3) for the present case ($R_0H \ll R_1I_1$). The term R_0H must be also taken into account for strong magnetic fields. The following equation thus holds for the Curie point itself ($T = \theta_f$):

$E/H = R_0 + R_1/\beta^{1/3}H^{2/3}$ (7), where β is the thermodynamic coefficient.

This equation makes it possible to determine R_0 in the experimental way. Experiments conducted by I. K. Kikoin (Ref. 5) in the range of high temperatures ($T \gg \theta_f$) showed that also in the paramagnetic region the Hall effect is determined by the magnetization I , and not by the magnetic field. In this case, $E = R_0H + R_pI$ (8) (R_p being the paramagnetic Hall constant). The dependence of the Hall emf on H is directly derived therefrom: $E = R^*H$ (9), and $R^* = R_0 + R_p\chi$ (10) (χ being the magnetic susceptibility which is practically independent of

Card 2/4

The Hall Effect in Ferromagnetics

83928
S/188/60/000/004/002/014
B005/B060

the magnetic field). The value of χ can be determined for temperatures above the Curie point with the well-known law by Curie - Weiss. Equation (10) describes the temperature dependence of the effective Hall constant R^* . K. B. Vlasov and S. V. Vonsovskiy (Ref. 6) showed that the susceptibility of ferromagnetic metals at temperatures above the Curie point consists of two components, one of which (χ_T) is dependent on temperature according to the Curie - Weiss law, while the other (χ_k) is practically independent of temperature and, in the absence of interactions between s- and d-electrons, passes over into the ordinary susceptibility of conduction electrons. The temperature-independent part of the effective Hall constant in equation (10) thus consists of two components: the "classical" constant R_0 and the constant $R_p \chi_k$ which, in its turn, is dependent on the susceptibility of conduction electrons. These two components are in different manners dependent on the density n of conduction electrons in the unit volume: R_0 is proportional to $1/n$, while $R_p \chi_k$ is proportional to $n^{1/3}$ according to Pauli. N. S. Akulov and A. V. Cheremushkina (Ref. 2), and N. V. Bazhanova (Ref. 4) are mentioned. ✓

ABSTRACT: The temperature dependence of the magnetic susceptibility of glass containing up to 13.8% Mn, 14.6% Co, and 14.5% Ni was measured. The initial glass (without addition of Mn, Co, or Ni ions) was diamagnetic, with a susceptibility of $-0.35 \cdot 10^{-6}$, practically independent of temperature. With the addition of the indicated ions, the glasses became paramagnetic and strongly temperature dependent. The reciprocal of the susceptibility proved to depend linearly on the temperature for all compositions of glass tested, but it was found not to be zero at absolute zero. This means that the relation does not simply follow the Curie law, but is rather expressed by the Curie-Weiss law: $\chi = \frac{C}{T-\theta}$, where χ is the susceptibility,

Card 1/2

ACCESSION NR: AP4028417

C the Curie constant, T the absolute temperature, and θ the Weiss constant. The observed linear dependence was found to hold only at low temperatures. At high temperatures the relationship is destroyed, and the law ceases to hold, the changes in magnetic susceptibility becoming irreversible. Heating and cooling lead to different susceptibility values. This irreversible character holds for glasses containing any of the investigated ions, and this suggests that such behavior is due solely to changes in the framework of the glass itself. TITLE: Hall effect in ferromagnetic metals near the Curie point

SOURCE: Fizika metallov i metalovedeniye, v. 20, no. 3, 1965, 355-360

TOPIC TAGS: ferromagnetic material, Curie point, nonferrous metal, Hall constant, nickel base alloy, molybdenum containing alloy

ABSTRACT: The dependence of the Hall field on the true magnetization of ferromagnetic materials was investigated theoretically by Ye. I. Kondorskiy (ZhETF, 1965, 48, 506). Experimentally, the Hall effect was studied in Ni-Mo alloys (≤ 5 atom% Mo) near the Curie point in a magnetic field, where the magnetization of samples was controlled mostly by true magnetization. The experiments showed that (1) the anomalous Hall field was proportional to true magnetization; (2) the constant R_1 , describing the Hall field in the region of true magnetization, had an absolute value higher than the Hall spontaneous constant R_s , i.e. $|R_1| > |R_s|$; (3) the R_1 and the spontaneous magnetization I_s were related

by $|R_1| = |R_p| + aI_s^2$ (R_p is a constant in the paramagnetic region); and (4) at $I_s \rightarrow 0$; the R_1 , as did the R_3 , tended to acquire the value of the Hall paramagnetic constant, i.e. $\lim_{I_s \rightarrow 0} R_1 = R_p$. The Hall constant in the region of the Curie point had no maximum. It passed gradually into the paramagnetic region. The maximum of the Hall constant in the region of the Curie point, observed in some experiments, was caused by the fact that the determination was made of the effective Hall constant which depends on susceptibility. The effective Hall constant has a sharp maximum in the region of the Curie point. The Hall constants R_p and R_0 (Hall field constant) depended differently on the content in alloy of the nonferromagnetic component. The R_p increased monotonically with increased concentration of M_0 in the alloy, whereas the R_0 had a maximum at a definite alloy composition (1.8 atom% of M_0). This experimental study substantiated the theoretical conclusions of V.S.I. Kondorskiy, to whom the authors are thankful for advice during the interpretation of the results. TITLE: Temperature dependence of the Hall effect in Ni - Mo alloys

SOURCE: Fizika metallov i metallovedeniye, v. 17, no. 6, 1964, 839-844

TOPIC TAGS: Hall effect, Curie point, ferromagnetic metal, electrical resistivity, magnetic saturation, phonon scattering, Ni, Mo alloy

ABSTRACT: Neither experimental nor theoretical data provide information on the laws governing the spontaneous Hall effect near the Curie point where the processes of scattering on magnetic impurities are of significance. The authors studied the Hall effect in Ni - Mo alloys containing 1.2; 2.5 and 5 at% Mo. The electrical resistivity and magnetic saturation I_s^2 as affected by temperature were investigated within a room temperature - Curie point range. Observations below the Curie point were useful for the verification of the current theory of effect in ferromagnetic metals. Since a linear relationship exists between the spontaneous Hall coefficient R_s/ρ and ρ the former may be described by
$$R_s = \alpha f + b\rho^2.$$

Card 1/3

L 16454-65
ACCESSION NR: AP4042040

In the direct neighborhood of the Curie point where the changes in electrical resistivity are highest in accordance with temperature, the Hall coefficient R_H is independent of ρ while it remains constant. The authors also established a linear dependence between R_H and I_G . They conclude that along with the phonon mechanism of scattering, the mechanism of scattering on magnetic inhomogeneities participates in the Hall effect and plays a particular role near the Curie point. The authors recommend additional theoretical studies of the spontaneous Hall effect near the Curie point. Orig. art. has: 2 figures.

TITLE: Temperature dependence of the magnetic susceptibility of manganese-copper alloys

PERIODICAL: Zhurnal eksperimental'noy i teoreticheskoy fiziki, v. 43, no. 2(8), 1962, 370 - 375

TEXT: The magnetic properties of Cu-Mn alloys show peculiarities, the causes of which have so far not been fully clarified. The authors studied $\chi(T)$ between 77 and 1250°K for Mn concentrations from 5.76 - 91.2 at.%. Measurements were made by the weighing method. The alloys were fused in an evacuated h-f furnace. At low temperatures, all alloys show an anti-ferromagnetic transition (Neel point θ_N); θ_N lies the deeper, the lower the Mn content; from 50% Mn upward, it remains constant at about 150°K. The course of the curves $\chi^{-1}(T)$ showing a minimum at θ_N depends on the Mn content: up to 17%, they are linear between θ_N and the melting point,

Card 1/2

f

Temperature dependence of the ...

S/056/62/043/002/002/053

as from 22% between θ_N and room temperature. They show a salient point at room temperature, and go on linearly up to the melting point. The inclination of these straight lines is the greater, the higher the Mn concentration. Resistivity maxima occur at these critical temperatures. Alloys containing 82.5 and 91.2 at% Mn show an abnormal behavior of $\chi(T)$: χ grows with the temperature. The experimental results can be explained by assuming that conduction electrons participate in the exchange interaction. There are 5 figures.
