The radiation vulcanization of ...

plotted versus temperature in the 40 - 200°C range. The effect of irradiation on mixtures of rubbers with polyethylene or polystyrene is that cross-linking occurs between the two polymers, to form substances with valuable physical and mechanical properties: the plasticity is greatly reduced, while the strength, wear-resistance and heat-resistance are improved. Abstracter's note: Complete translation.

ABSTRACT: An analysis is shown of two methods of derivation of the forces in the calculation of the stability of rigid structures and earthen slopes on circular-cylindrical or other slippage surface: Terzaghi (wherein the direction of the forces of interaction between the soil sectors is directed along the tangent to a segment of a circular-cylindrical slippage surface) and Crea (wherein the direction of the interaction force between the soil sectors is horizontal), with preference given the Crea method. In connection therewith, the Authors have developed a proposition relative to the calculation of the coupling

TITLE: The Operation of an Alluvial Buttress Dam in Complex Hydrogeological Conditions (Rabota namyvnoy podpornoy damby v slozhnykh gidrogeologicheskikh usloviyakh)

PERIODICAL: Izv. Vses. n.-i. in-ta gidrotekhn., 1955, Vol 54, pp 126-139

ABSTRACT: This is the conclusion of a paper bearing the same title and written by the same authors (RzhMekh, 1955, abstract 3157). Following a rise in the headwater level to 50 cm above the normal design level, observations afforded a more accurate picture of the seepage through the foundation of the dam; measures for the improvement of its operation are outlined. Various problems of the stability of the dam and various aspects of the seepage and the hydrochemical and hydrothermal comportment of the dam, as well as the mechanical piping, are examined.

TITLE: A Possibility of Constructing a Fast Amplitude Analyzer.
(Ob odnoy vozmozhnosti postroyeniya bystrodeystvuyushchego
amplitudnogo analizatora)

PERIODICAL: Radiotekhnika i Elektronika, 1957, Vol.2, No.4,
pp. 507 - 509 (USSR)

ABSTRACT: The proposed system is based on the principle of quantizing the signal (pulse) by means of a regenerative circuit, in which the number of the stable states is equal to that of the analyser channels. The system consists of a pulse-lengthening circuit, a deflection amplifier, a quantizing cathode-ray tube, an output amplifier, a gate generator, a storage tube with a gate generator and a time base, and an adding circuit. Functioning of the system is briefly described and its block schematic is shown. An experimental analyzer of this type was constructed; it had 25 channels and its quantizing time was about 0.5 μ sec.

icheskiye zapominayushchiye ustroystva)

PERIODICAL: Pribory i tekhnika eksperimenta, 1958, Nr 5, pp 35-40
(USSR)

ABSTRACT: The characteristics of the input device of a multi-
channel pulse height analyzer with a periodic recorder are
such that one cannot use the well-known formulae, based on
the concept of the resolving time, to obtain counting losses.
The confusion which exists in this connection has led the
author to try and obtain an analytical expression connecting
the integral counting rate recorded ν_p and the mean
repetition frequency of the pulses ν . The counting losses
 Δ are then given by $\Delta = \nu - \nu_p$. General formulae are
given which connect the integral counting rate and the mean
repetition frequency of the incoming pulses for 4 types of
pulse height analyzers, using periodic memory devices. These

Card 1/2

SOV/120-58-5-9/32

Counting Losses in Multi-Channel Pulse Height Analyzers Using
Periodic Memory Devices

four types are due to Sanin (Ref.1), Scarrott (Ref.2),
Schlutz et al (Ref.3), and a scheme developed at the Lenin-
grad Electrotechnical Institute respectively. The formulae
obtained may be used to determine the counting losses and
also as criteria in choosing the frequency of the incoming
pulses, depending on the type of the input device used in
the particular analyzer. There are 6 figures and 3 refer-
ences, 1 of which is Soviet and 2 are English.

TITLE: A Non-Overloading Amplifier with a Wide-Channel Discriminator
(Neperegruzhayushchiysya usilitel' s shirokokanal'nym
diskriminatorem)

PERIODICAL: Pribory i tekhnika eksperimenta, 1958, Nr 5, pp 40-44
(USSR)

ABSTRACT: The device described consists of the following principal parts: 1) a non-overloading linear amplifier comprising a pre-amplifier, a phase inverter, pulse-forming networks, an output amplifier and a power amplifier; 2) an integrating wide channel pulse discriminator consisting of a lower and upper gate, a charging diode, a resetting triode, an anti-coincidence circuit, the output univibrators of the integrating and differentiating channels followed by power amplifying stages; 3) supply sources. The non-loading amplifier is based on the circuit described by Fairstein (Ref.3) and its circuit diagram is shown in Fig.1. The pre-amplifier of

Card 1/3

SOV/120-58-5-10/32

1 Non-Overloading Amplifier with a Wide-Channel Discriminator

this unit is based on a cathode coupled circuit, while the phase inverter consists of one tube with anode and cathode resistances. The pulses are formed after the inverter by means of RC networks or by a short circuited delay line (.5 μ sec duration). The final amplifier consists of 5 tubes; the first 3 form a "triple" and are provided with a negative feedback; the 4th tube operates as a cathode follower. The output signal of the amplifier is applied to an external pulse analyser and to the discriminator of the device. The discrimination level can be varied from 5 to 105 V in steps of 1 V; the voltage divider circuit is shown in Fig.2. The instrument is designed for the operation with a scintillation counter. The maximum gain of the amplifier is 2×10^6 and the effective noise amplitude at the output of the amplifier is less than .04 V. The pulse rise time is .15 μ s and the pulse duration is: a) 2, 5, 10 or 20 μ s if RC networks are used, and b) 1 μ s if a delay line is used. The overloading coefficient of the amplifier is over 100. The amplifier is asymmetrical in that it does not amplify negative pulses. The amplitude characteristic of the

Card 2/3

SOV/120-58-5-10/32

A Non-Overloading Amplifier with a Wide-Channel Discriminator

amplifier is shown in Fig.3, from which it is seen that its output is linear from 2 to 120 V. The instrument is supplied with +300 V at 130 mA and with -250 V at 20 mA. The paper contains 3 figures and 3 English references.

TITLE: A Counting Instrument Employing Dekatrons (Pereschetnyy
pribor s ispol'zovaniyem dekatronov)

PERIODICAL: Pribory i tekhnika eksperimenta, 1958, Nr 6, pp 78-81
(USSR)

ABSTRACT: Since a dekatron is a comparatively new device and since its parameters depend to a large extent on the trigger circuit employed to effect the transfer from one cathode to the next, a detailed investigation of the triggering methods was carried out. The authors tried a number of triggering circuits and found that the most successful one was that employing a double triode in which one of the anodes was provided with a delay capacitance; the circuit is shown in Fig.12. The dekatron employed was of the type 10/SG1S and had 2 systems of guide electrodes. The actual counter (see the diagram of Fig.5) consisted of the following elements: 1) a binary counting decade based on vacuum tubes, 2) 4 counting decades based on dekatrons, 3) a timer, 4) a circuit for controlling the timer and the input gate circuit, 5) a gating circuit, 6) an intensity meter, 7) a quartz crystal calibrator, 8) a power supply source, and 9) a mechanical register.

Card 1/3

SOV/120-58-6-15/32

A Counting Instrument Employing Dekatrons

The operation of the equipment is as follows. An input pulse is applied to the gating circuit which is in the form of a univibrator; the circuit can be blocked by the bi-stable device which also controls the timer. The pulses from the anode of the gating univibrator are applied to the binary decade. The output from the decade is used to trigger the first dekatron, which in turn drives the following dekatrons. The counting can be stopped automatically after a pre-set time interval which is determined by the timer. The basic time intervals are 3, 6 and 15 sec; by employing 2 dekatrons it is also possible to obtain counting intervals of 60, 150, 300, 600 and 1500 sec. The average counting rate is recorded by the intensity meter which is capable of measuring the rates ranging from 200 to 5×10^4 pulses per minute. The instrument can be checked by employing the quartz

crystal oscillator which operates at 75 kc/s. The device has a resolving time of 12 μ s. The authors express their gratitude to Yu. A. Nemilov for making this work possible and for his interest in it. The paper contains 8 figures and 4 references; 2 of the references are English and 2 are Soviet.

TITLE: Linear Pulse Gate Circuit (Skhema proportsional'nogo
propuskaniya impul'sov)PERIODICAL: Pribory i tekhnika eksperimenta, 1959, Nr 2, p 117
(USSR)

ABSTRACT: The arrangement described in Ref 1 uses special beam-deflection valves. The present circuit, Fig 1, contains only standard pentodes 6P 15 P. Until the arrival of the gate pulse at the grid of Λ_2 the anode current of Λ_1 flows through Λ_2 , Λ_4 and Ra. If a signal should arrive at the grid of Λ_1 the increase in anode current does not evoke a change in output voltage since the anode of Λ_2 is effectively earthed via the capacitance of 0.25 μ f. There is no direct transmission through the feedback path R_1 , R_2 , C_1 since the output resistance of the cathode follower Λ_5 , Λ_6 is small. When a gate pulse is applied the anode current of Λ_1 switches from Λ_2 to Λ_3 . If at the same time a signal pulse arrives then Λ_1 works as an anode follower. The circuit passes

TITLE: Amplitude Analyzer of Nuclear Radiation Spectra

PERIODICAL: Izv. Leningr. elektrotekhn. in-ta, 1959, No. 38, pp. 237-248 ✓

TEXT: The authors investigate the limitations and advantages of using various memory devices in amplitude analyzers. A description is given of the "AMA-3c" (AMA-3s) type automated multi-channel amplitude analyzer with an electrostatic storage tube as memory device. This model was exhibited at the Geneva Exhibition in 1958. It possesses the following technical data: number of channels - 128; capacity of each channel - 2^{16} , resolving time $0.5 + 22 \mu\text{sec}$ ($n = \text{channel number}$). The results are read on the monitor screen in the form of binary numbers or as histogram. The analyzer can operate with external control pulses (under coincidence or anticoincidence conditions). The number of tubes is 130, power consumption is 850 w.

TOPIC TAGS: analyzer, pulse height analyzer, miniature analyzer, dynamic memory, magnetostriiction delay line, nuclear instrumentation

TRANSLATION: A description of the multichannel pulse-height semiconductor AMA-5 analyzer is presented. The analyzer is intended for use under difficult plant and field conditions. It employs a miniature part and printed wiring. The total number of elements has been

Card 1/2

ACCESSION NR: AR4014747

reduced in AMA-5 to ~1200. Such a reduction has been made possible by maximum utilization of each element. The analyzer employs a dynamic memory with a magnetostriction delay line. The memory (2048 μ sec) is broken up into 128 16-digit memory cells (channels) without pauses between them. The information readout is by a read-out block in three forms: a table of binary numbers, a linear-scale histogram on a cathode-ray tube screen, and a histogram on a paper chart. The maximum counting rate of the analyzer is 3000 pulses per second. L. S.

AUTHORS: Vyazemskiy, V.O., Pisarevskiy, A.N. and Selyaninov,
Yu.Ye.

TITLE: Single channel differential discriminator for the
coincidence circuits of the scintillation counters

PERIODICAL: Pribory i tekhnika eksperimenta, no.4, 1961, 64-66

TEXT: The authors have designed and tested a single channel
differential discriminator for work with fast coincidences circuits
employing slow scintillators. In order to eliminate the effect of
the build-up time of the investigated pulse on the resolution time
of the coincidence circuit, a saturated amplifier has been used as
described earlier by G. P. Mel'nikov (Ref.1: PTE, 1959, No.5, 61).
In this arrangement the investigated impulse is fed simultaneously
to the input of the expander and to the saturated amplifier. The
latter is stable under overload conditions. The signal emerging
from the saturated amplifier triggers the Schmidt trigger circuit
which in turn sends an impulse via the cathode follower into the
delay and pulse shaping lines, where it is shaped into a short
pulse corresponding to the leading edge of the saturated pulse. The

length of the delay is chosen to match the scintillation time of the phosphors. A detailed circuit is given in Fig.1, which shows the main circuit of the discriminator. (Correction: change the anode loads of the R.H.S. of valves 6 and 7 to 2.2 kohms, and the grid resistance of the L.H.S. to 100 kohms) (8Х00 - input, 8б1Х00 - output, 8Н2ШНС СМЕЩЕНИЕ - external bias, 11WМ - 11 off [Abstractor's note: meaning 11 resistors in series.] With the working parameters given, the threshold of the discriminator may vary from 5 - 105 V; the width of the window is adjustable in 1 V steps from 1 - 10 V, and then to 14, 16, and 20 V. The threshold value and the window width were found to remain stable to within 1%, after 8 - 10 hours of work. The dead time of the instrument (for a given case) was approximately 3 μ sec. The duration of the output pulses measured at half peak, were estimated as 0.1 μ sec, and their amplitude was 5 V (for both polarities). When the amplitude of the investigated pulses increased from 5 to 125 V, the time spread of the centroids of the output pulses was less than 5×10^{-8} sec. There are 1 figure and 5 references: 2 Soviet and 3 non-Soviet. The English-language references read as follows: Ref. 3: W. Gruhle,

AUTHOR*: Vorob'yev, Yu. V., Vyazigin, A. A. SOV/20-126-6-28/67

TITLE: On the Chromatic Aberration Field in the Electron Microscope
(O polevykh khromaticheskikh aberratsiyakh v elektronnom mikroskope)PERIODICAL: Doklady Akademii nauk SSSR, 1959, Vol 126, Nr 6, pp 1248 - 1249
(USSR)ABSTRACT: Earlier papers (Refs 1 and 2) had shown that the chromatic aberration field may be corrected by an appropriate choice of current strength and voltage in the electron microscope lenses. The present paper deals with the investigation of the chromatic aberration field of an electron microscope, in which the axes of the lenses are individually displaced with respect to one another. Formulas (1) give the displacement of the image of any arbitrary object point by a change in the accelerating voltage by ΔU . Formula (2) serves for the determination of the section of the total chromatic aberration field in the axial optical system, and formula (3) the same for nonaxial optical systems. In the case of electron microscopes with high resolving power, however, chromatic aberration is very slight, and therefore, a correction is not necessary. It is further

Card 1/2

On the Chromatic Aberration Field in the Electron Microscope SOV/20-126-6-28/67

stated that the chromatic aberration may, in consequence of bad collimation, be decreased only by a better collimation and a steadier accelerating voltage. There are 2 references.

TITLE: Influence of aberrations on image quality under conditions for realizing the ultimate resolution of an electron microscope /Report, Fifth All-Union Conference on Electron Microscopy held in Sumy 6-8 July 1965/

SOURCE: AN SSSR. Izvestiya. Seriya fizicheskaya, v. 30, no. 5, 1966, 730-734

TOPIC TAGS: electron optics, electron microscope, spherical aberration, astigmatism, chromatic aberration, image contrast, optic resolution

ABSTRACT: It has previously been shown by the authors (Izv. AN SSSR. Ser. fiz. 27, 1122 (1963)) that the ultimate resolution of an electron microscope can be improved only by reducing the spherical error or increasing the accelerating potential. In the present paper the authors use the methods and results of their earlier paper to calculate the effects of axial astigmatism, defocusing, and chromatic error on the image contrast and resolution of an electron microscope. The results are presented graphically and in tabular form and are discussed. It is found that image contrast deteriorates more rapidly than resolving power with increasing axial astigmatism or defocusing. If one decreases the spherical aberration, the chromatic aberration de-

Card 1/2

L 36549-66

creases also. It is concluded that it is not necessary to improve the stability of the power supplied of modern first class electron microscopes in order to realize the improved resolution that might be made possible by a decrease of their spherical aberrations. TITLE: Scattering of electrons on heavy atoms

SOURCE: Optika i spektroskopiya, v. 21, no. 6, 1966, 666-672

TOPIC TAGS: electron scattering, electron microscopy, atomic electron scattering, atomic radius computation, spectroscopy, electron optics, self consistent field method, Thomas Fermi model, Slater model

ABSTRACT: The scattering of electrons at small angles plays an important part in the formation of images in electron microscopy. A method is proposed for computing the mean square of the radius of a heavy atom based on a self-consistent field, which makes it possible to determine electron scattering at small angles. A comparison is made between values obtained for the mean square of atomic radii using the proposed method, and those obtained by the Thomas-Fermi and Slater models.
