<p><i>*On the Nature of the Cathodic Polarization of Zinc. O. Edin (Zhur. Fiz. Khim., 1943, 17, (3), 159-168).—[in Russian.] The polarization of zinc was studied by using a streaming mercury electrode. Three series of experiments (in sulphate, zincate, and cyanide electrolytes) are described, and the results are given in tables and graphs. It was shown that (a) a slow discharge of zinc takes place when using a sulphate solution, (b) cathodic discharge is accompanied in the case of alkaline and cyanide solutions by the slow dissociation of complex ions. — V. ABSTRACT: AND PROPERTIES INDEX

The mechanism of the corrosion of iron by sulfur  
P. V. Gel'd and O. A. Esm. *J. Applied Chem. (U.S.S.R.)*  
19, 678-83 (1946) (in Russian).— A parallel is drawn be-  
tween the corrosion of Fe by S and the oxidation by gases  
(O<sub>2</sub>, CO<sub>2</sub>, H<sub>2</sub>O). Here and there, an oxide (sulfide) scale  
of variable compn. is formed on the surface; further corro-  
sion is detd. in the main by diffusion of Fe ions. On  
the basis of the FeS-FeS<sub>2</sub> equil. diagram, the inner layer  
of the sulfide scale is assumed to be close to pyrrhotite,  
the outer layer to pyrite; the essential role in the  
corrosion mechanism is ascribed to solid solns. of S in  
troilite the hexagonal lattice of which exhibits a hole  
structure, corresponding to missing Fe atoms, with the  
lattice const. falling from 50.81 to 52.25 Å. between 50  
and 55.5 at. % S; in corrosion, Fe ions diffuse in the di-  
rection from the innermost layer where the "hole concn."  
is lowest, towards the zone of higher hole concn. facing the  
pyrite layer; the "solid soln. of holes" corresponds to  
FeS<sub>2</sub> at 0.5 at. % in FeS<sub>2</sub> at 100%. The sulfide layer  
grows in thickness in both directions on account of the  
consequence of the variable, deeper, pyrrhotite-troilite  
zone, progressively enriched with Fe ions, and the pyrite  
layer; accordingly, the observed vol. increase is higher  
than might be expected from a conversion of Fe into FeS.  
The Fe-S system has a wider range of compn. (i.e., a  
wider range of "hole concn.") than the Fe-O system,  
hence the rapid growth of the sulfide corrosion layer.

**Mechanism of the protective action of alloying elements in sulfidic corrosion of iron.** P. V. Gel'd and O. A. Esin. *J. Applied Chem. (U.S.S.R.)* 19, 861-8 (1946) (in Russian); cf. *C.A.* 41, 4403a. — In an alloy steel, the compn. of the surface sulfide layer will generally change with its growth, depending on the relative values  $D_{Fe}$  and  $D_{Mn}$  of the diffusion coeffs. of the ions of Fe and of the alloying element, resp. If  $D_{Fe}$  is less than  $D_{Mn}$ , the outer face of the sulfide film will become progressively richer in Fe and the inner face progressively richer in the alloying element. Corrosion will be counteracted if the change in compn. results in a film with a higher energy of embrittlement. The relative  $D$  are linked with the values of the lattice energies  $U$  of the resp. sulfides, the types of the lattices, and the ratios of the sizes of the ions and the lattice parameters. If, in addn. to a higher  $U$ , the sulfide of the alloying element forms a lattice similar to that of troilite, its atoms will penetrate into the holes of the deficient Fe sulfide lattice with the result that a more compact protective film will be formed. These conditions are fulfilled in the case of Cr, known to afford corrosion protection (at a concn. of at least 12%) to steel in  $H_2S$ ; this is also the threshold of Cr content for protection against oxidic corrosion where Cr has been shown (Pfeil, *C.A.* 23, 3196; 25, 4508) to accumulate at the inner face of the corrosion film. In corrosion by S, the protective action of Cr similarly consists in the formation at the inner face of the film of a concd. solid soln. of CrS in FeS with the hole concn. substantially lowered. Ultimate

9

formations of the spinell type, after oxidation of  $Cr^{++}$  to  $Cr^{+++}$ , are probable. In the case of an element with  $U$  of the same order as that of FeS and a similar lattice, an adequately protective sulfide layer can still be formed if the ions of the alloying element are considerably smaller than  $Fe^{++}$  and hence are able to penetrate the lattice and evict Fe; this lowers its deficiency and results in greater compactness. On the basis of these considerations Ni should be an effective alloying element. Actually, a Ni content does protect against oxidic corrosion but fails against S, owing to the low m.p. of NiS (810°) and particularly to that of the Ni-NiS eutectic (644°). A marked difference of the crystal lattices of the sulfides must result in failure of the alloying element to reconstruct the deficient FeS layer, even if the  $U$  are close and the ion radii fairly close. This case is illustrated by Mn, which (at 2%) is actually known not to afford protection against corrosion by S and to accumulate only to a slight extent at the inner face of the film. A 4th. type of alloying element, characterized by a high  $U$  as compared with FeS, a markedly different lattice, and distinctly smaller ion size, can protect through accumulation not at the inner but at the outer face of the sulfide film. This type is exemplified by Al, the beneficial effect of which is due to the greater readiness of its diffusion (as compared with Fe) to the external surface, where it can react freely with the oncoming S to form the high-melting (1100°)  $Al_2S_3$ , even though it is unable to reconstruct the deficient FeS layer.

ASB-SLA METALLURGICAL LITERATURE CLASSIFICATION

**Dissociation of oxides in the course of their reduction.**  
 P. Gels and O. Ikin. *Bull. Acad. Sci. U.R.S.S., Chem. Sci. Ser.* 1946, 800-812 (in Russian). — The point of view represented by A. P. Lyuban (*ibid.* 1948, 11) according to which the first step in the reduction of a metal oxide is its dissociation, with subsequent reaction between the free  $O_2$  and the reducing agent in the gas phase, is refuted. In the first place, equil. dissociation pressures of  $O_2$  at moderate temp. (at which reduction is found to be measurably fast) are in many cases, such as that of  $FeO$ , so low as to have only thermodynamic, not statistical, reality. From the kinetic point of view, with assumptions most favorable to the two-stage dissociation-reduction theory, namely instantaneous dissociation, followed by instantaneous gas-phase reaction, and a rate of escape of  $O_2$  from the surface into the gas phase governed by the gas-kinetic root mean square velocity, and by assuming a surface area for  $FeO$  of 1 sq. m./g., the times of complete reduction calcd. for 827°, 727°, and 627° are of the order of  $10^{14}$ ,  $10^9$ , and  $10^4$  yrs., resp. The two-stage theory is furthermore refuted by the fact that the rates of reduction of  $FeO$  by  $CO$  and by  $H_2$  are different, whereas their rates of gas-phase combination with  $O_2$  are very close. The latter reaction is not slowed down and often accelerated by small amounts of its products,  $CO_2$  and  $H_2O$ , whereas the corresponding reduction reactions are inhibited by small amounts, and very little affected by large amounts, of the products. Reduction of  $Fe_2O_3$  by  $CO$  starts at 150° where there is no measurable reaction  $CO + O_2$ . The representation of Chaudron's reaction  $3FeO + CO_2 = Fe_2O_3 + CO$  as proceeding over  $FeO = Fe + O$ , followed by  $CO + O = CO_2$ , and  $3FeO + O = Fe_2O_3$ , is refuted on similar grounds: under most favorable conditions, production of 1 g.  $Fe_2O_3$  by this mechanism at 500° can be shown to require  $10^{14}$  yrs.

As equilibrium is reached, 12 min.; what is more,  $FeO$  is converted at that temp. into  $Fe_2O_3$ , to a (measurably) observable extent, in a few days. The two-stage mechanism further fails to account for the catalysis by metallic  $Fe$  of Hall's reaction  $3CO = C + CO_2$ ; the necessary assumption of the elementary steps  $CO = C + O$ ,  $Fe + O = FeO$ ,  $FeO = Fe + O$ , and  $CO + O = CO_2$  is contradicted, among others, by the absence of an effect of  $H_2O$  vapor and of the radiation characteristic of excited  $CO_2$ . Calcn. of the rate by this mechanism leads, at 500°, to  $10^{14}$  yrs. for the decomposition of 1 g.  $CO$ , as against an expd. 8 hrs. A homogeneous reduction mechanism being thus excluded, correct interpretation is only possible in analogy with Taylor's activated-adsorption mechanism of the  $NH_3$  synthesis, by a reaction between adsorbed  $CO$  and  $CO$ . In support of this mechanism, there is the similarity of mol. structure and energy data for  $N_2$  and  $CO$ ; catalysis by  $Fe$  of all the 3 reactions  $N_2 + H_2$ ,  $CO + CO$ ,  $H_2 + O_2$ , and inactivation of the catalyst at 550-650° in all 3 cases. However, the similarity between the  $N_2 + 3H_2 = 2NH_3$  and the  $3CO = C + CO_2$  reactions holds only in the early stages of the latter; with its progress, a graphite lattice is built up and  $O$  atoms are dissolved in it; under favorable conditions,  $CO$  from the graphite will react with  $O$  atoms and form  $CO_2$ . Reduction of metal oxides by  $CO$  and by  $H_2$  runs over an activated-adsorption mechanism the first step of which consists in adsorption of the reducing agent by the oxide surface, and the reduction is brought about in the adsorbed state.

48

The electrolytic nature of liquid technical  $\text{CaC}_2$  (calcium carbide). P. V. Gel'd, O. A. Rahn, and P. N. Maron (N. M. Kirov Ural Ind. Min., and Ural Chem. Research Inst., Sverdlovsk). *J. Applied Chem. (U.S.S.R.)* 21, 251-9 (1948) (in Russian). — (1) The elec. resistance  $\rho$  of solid tech.  $\text{CaC}_2$ , contg. large amts. of  $\text{CaO}$ , falls sharply after refusion in an induction furnace. Thus for "carbides" contg. 60.1; 67; 69; 71.4%  $\text{CaC}_2$ ,  $\rho$  was found = 330; 700; 10,400; 3130 ohm. cm. After fusion, for  $\text{CaC}_2$  43 and 60.3%,  $\rho$  = 0.6 and 1.4, resp. (at 25°). The drop of  $\rho$  with rising temp. is illustrated by the data for a sample with 60%  $\text{CaC}_2$ : at 25; 100; 300; 730; 850; 1121°,  $\rho$  = 10,400; 5,400; 1000; 100; 8.3; 1.5, on cooling, at 900; 690; 500°,  $\rho$  = 10.7; 30; 35 ohm. cm. After heating at a const. temp. of 1030°, for 0, 60, 120, and 180 min.,  $\rho$  at 25° was 3240, 328, 112, and 83. The results might be interpreted in terms of the existence of 3 different modifications of  $\text{CaC}_2$  (Frank, *et al.*, *C.I.* 31, 5290) of which  $\text{CaC}_2$  I has an electrolytic cond. More plausibly, in the light of the phase diagram  $\text{CaC}_2$ - $\text{CaO}$  (Plum and Aall, *J. Amer. Chem. Soc.* 66, 317 (1935); *C.I.* 29, 8025), an oxycarbide,  $\text{Ca}_2\text{C}_3\text{O}$ , which can be described as the Ca salt of graphitic acid (Hofmann and Holst, *C.I.* 33, 4975) can be formed in the presence of high contents of  $\text{CaO}$ ; formation of the oxycarbide lattice, with cations  $\text{Ca}^{2+}$  and anions  $(\text{C}_3\text{O})^{2-}$ , being slow, tech. carbide will be constituted mainly by the ionic lattices of  $\text{CaC}_2$  and  $\text{CaO}$ , with anions  $\text{C}_2^{2-}$  and  $\text{O}^{2-}$ , and exhibit distinctly ionic cond., whereas upon re-fusion, owing to increased formation of the oxycarbide lattice, electrolytic cond. will reveal and electronic cond. appear. This is borne out by the fact that

high (electronic) cond. appears the easier, the nearer the  $\text{CaO}$  content is to 50%. Thus,  $\text{CaC}_2$  I is an ionic conductor, while the cond. of solid  $\text{CaC}_2$  II and  $\text{CaC}_2$   $\text{CaO}$  is most probably mixed, ionic-electronic. (2) In the liquid state, electronic cond. disappears and becomes purely ionic, as evidenced by the order of magnitude of the sp. cond., a few tenths of ohm<sup>-1</sup> cm.<sup>-1</sup>, comparable to that of fused silicates and slags; the viscosities of fused tech. carbide and of slags and silicates are likewise of the same order of magnitude. In analogy with silicates, the ionic cond. is attributed to small ions,  $\text{Ca}^{2+}$ ,  $\text{C}_2^{2-}$ , and  $\text{C}_3\text{O}^{2-}$  (in oxycarbide), whereas the high viscosity indicates large, resulting in association of the simple anion into large aggregates such as  $\text{C}_4^{2-}$  and, especially,  $\text{C}_6^{2-}$ , the latter representing a six-membered element of the graphite lattice and aggregating further into graphite-like layer ions  $(\text{C}_2)_n^{2-}$ . Similarly, the simple  $\text{C}_3\text{O}^{2-}$  anions aggregate into  $(\text{C}_3\text{O})_n^{2-}$ , which may partly dissociate into the aggregation products of  $\text{C}_2^{2-}$  and  $\text{O}^{2-}$ . Changes from  $(\text{C}_3\text{O})_n^{2-}$  to  $(\text{C}_2)_n^{2-}$  and  $\text{O}^{2-}$  anions are responsible for the fact that tech. carbide of a composition close to  $\text{CaC}_2$  has a higher viscosity than carbides with a higher content of  $\text{CaC}_2$ .

ca 4

Effect of silicic acid on the equilibrium between liquid iron and the simplest basic slags. Orskov (Ural Ind. Inst., Sverdlovsk). *J. Phys. Chem.* (U.S.S.R.) 22, 187-23 (1948).—The theory of perfect ionic solns. (cf. Temkin, *C.A.* 40, 5021) is applied to literature data on the equil. in the two-phase systems Fe, metal, O/FeO, metal oxide, and Fe, metal, O/FeO, metal oxide, SiO<sub>2</sub>. In the absence of SiO<sub>2</sub>, the theory is fulfilled when the metal is Mn, Ni, or Co, i.e. a metal similar to Fe in the dimensions and polarizability of its ions. When the metal is Ca, electrostatic effects on the coeff. of activity must be taken into account. In the presence of SiO<sub>2</sub>, even similar cations behave differently. This is attributed to a relatively regular structure within the slags (cf. *C.A.* 41, 6312g). J. J. Bikerman

Effect of silicic acid on the equilibrium between liquid iron and the simplest basic slags. (1) *Rain, D. D. (1948). Nauk. S.S.S.R. 59, 280-92 (1948); cf. C.A. 42, 6717.* Distribution of oxygen between the metal and the basic slag from the point of view of the ion theory. (2) *Rain and V. Koshchurov. Zhur. Priklad. Khim. (J. Applied Chem.) 21, 705-74 (1948).* (1) The data of Chipman, *et al.* (Petters and C., C.A. 35, 3572; Jette, *et al.*, C.A. 35, 7004; Grant and C., C.A. 40, 3083) were utilized to compute the const.  $K_0 = N_{Fe^{2+}} N_{O^{2-}} / [FeO]$ , where  $N$  = mole fraction in the slag,  $[FeO]$  = wt. % of  $O$  dissolved in the metal. The ionic comp. of the slags was calc. on the assumption of complete dissoc. into ions, with all of the  $SiO_2$  present in the form of  $SiO_4^{4-}$  and all of  $FeO$  in the form of  $FeO^{2+}$ ,  $Al_2O_3$  in the form of  $AlO_4^{3-}$ , and  $P_2O_5$  in the form of  $P_2O_7^{4-}$ . The values of  $K_0$  from the expl. data at 1840, 1880, and 1720° are plotted as a function of  $x = 1 - N_{O^{2-}}$ . The point of intersection with the axis of ordinates was detd. by applying the empirical formula of Taylor and Chipman (C.A. 35, 6978), giving, at  $x = 0$ ,  $\log K_0 = (63.3/7) - 2.731$ . The expl. points are fairly satisfactorily grouped around a curve calc. by  $\log K_0 = \log K_0' - 0.4x - 1.4x^2$ , with max. deviations not exceeding 20-30%. (2) The mean activity coeff.  $f_a$  of  $FeO$  follows from  $\log f_a = 1/2(\log K_0' - \log K_0) = 0.2x + 0.7x^2$  (equation 1), practically independent of the temp.; thus,  $f_a \approx 1$  and decreases with increasing  $N_{O^{2-}}$ . These formulas are applicable only for slags characterized by  $ZnO/Zn_{ox} \geq 2$ , where  $ZnO$  = sum of no. of moles of all basic oxides besides  $FeO$ ,  $Zn_{ox} = nSiO_2 + 1/2(nP_2O_5 + nFeO_3 + nAl_2O_3)$ . In particular, for the system  $FeO + CaO + SiO_2$ , the equation ceases to hold when  $n(CaO)/n(SiO_2)$  approaches unity, and it is not applicable to  $FeO + SiO_2$ . (3) The above relations can be explained qualitatively on the assumption that, in a system  $FeO + CaO + FeO_3$ , the relatively smaller and more polarizable cation  $Fe^{2+}$  interacts more strongly with  $SiO_4^{4-}$ , the latter undergoing splitting,  $2 SiO_4^{4-} \rightarrow Si_2O_7^{6-} + O^{2-}$ , as a result of which  $SiO_4^{4-}$  are rarefied around  $Fe^{2+}$  and are preferentially drawn close to  $Ca^{2+}$ . This situation, which can be described as an ordering within the fused electrolyte, is expressed by a coeff.  $h = h_1/h_2$ , where  $h_1$  and  $h_2$  measure the (unequal) energies of interaction of, resp.,  $Ca^{2+}$  and  $Fe^{2+}$  with  $O^{2-}$  ( $h < 1$ ). The deviation from statistical distribution, in a slag composed of  $n_1$  moles  $CaO$ ,  $n_2 FeO$  and  $n_3/2 SiO_2$ , is described by the statement that one has, around the  $Ca^{2+}$  ions,  $n_1 - [n_1/(n_1 + h n_2)] O^{2-}$  ions and  $n_1/2(n_1 + h n_2) SiO_4^{4-}$  ions, and around the  $Fe^{2+}$  ions,  $[n_2 - h n_1 n_2/(n_1 + h n_2)] O^{2-}$  ions and  $h n_1 n_2/2(n_1 + h n_2) SiO_4^{4-}$  ions. The no. of permutations around  $Fe^{2+}$  is less than it would be in a statistical distribution of the anions; consequently,  $f_a$  decreases slower than  $N_{O^{2-}} N_{Fe^{2+}}$ , and  $f_a$  will increase with decreasing  $FeO$ , i.e. with decreasing  $N_{O^{2-}}$ . Writing down the expressions for the no. of permutations  $W$  of anions around  $Ca^{2+}$  and around  $Fe^{2+}$ , and substituting in the expression for the entropy of mixing in terms of  $W$ , one finds, if the heat of mixing is zero and assuming  $h = 1/2$ ,  $f_a = \{0.5^{n_1} (1 - 0.5)^{n_2} (2 - s)^{1/2(n_1 - n_2)} (1.5 - s)^{1/2} \}^{1/2}$  where  $\gamma = (1 - s)^{1/2}/(2 - 1.5s)$  and  $s = N_{O^{2-}} = n_1/(n_1 + (n_2/2))$ . Values of  $f_a$  calc. by this equation, for  $s$  varying from 0.1 to 1.0, are in acceptable agreement with  $f_a$  from the expl. equation 1. In the extreme case  $h = 1$ ,  $f_a = N_{O^{2-}}$ .

If  $h = 0$ , i.e. the interaction of the other cation and is negligible,  $f_A = 1$  throughout to resolve this contradiction, one must take into account also permutations of the cations. (4) In this picture the preferential crowding of  $\text{SiO}_4^{4-}$  around  $\text{Ca}^{++}$  and their desertion of the neighborhood of  $\text{Fe}^{++}$  is detd. by a lesser interaction of  $\text{Ca}^{++}$  with  $\text{SiO}_4^{4-}$  as compared with  $\text{Fe}^{++}$ . This is also the reason underlying the lowering of the elec. cond. of fused  $\text{Fe}_2\text{SiO}_4$  by addn. of  $\text{Ca}_2\text{SiO}_4$ . (5) These considerations are applicable also to other anions, e.g., aluminates, phosphates, and ferrites. N. Thon

Thermographic and kinetic studies of dissoci-  
tion of dolomites and magnesium under various  
temperature and pressure conditions showed: (1)  
first step of dissociation of dolomites occurs  
48/49T17

Therm/Chemistry - Dolomites, Dissoc- Mar 49  
ciation of (Contd)

at stages lower than for magnesium, but (2)  
dissociated for both increases greatly at  
low pressures. Determined that there was no  
preliminary dissociation of dolomites in forma-  
tion of their carbonates. Corrections of  
thermograms made it possible to determine stages  
at which various calcium carbonates were formed.

Silicon losses on melting ferroalloys. P. V. Gel'd, O. A. Bain, N. N. Bulnov, and R. M. Lerinman (Kirov Urals Polytech. Inst.). *Doklady Akad. Nauk S.S.S.R.* 1973-8(1940); cf. *C.A.* 43, 1892h, 1897h. The nature of the phases involved in losses of Si on melting high-Si alloys was investigated. A solid phase that was almost pure SiO was collected from a melting furnace. The material richest in SiO was found at the charging level on the electrodes, etc., in the form of kidney-shaped sintered accretions with a glassy fracture; it appeared to have grown from the liquid state; it had a greasy green-yellow sheen, a hardness over 5; it was friable and had a fine grained fracture; its chem. analysis was SiO<sub>2</sub> (on the basis of SiO) 125-8%, Fe<sub>2</sub>O<sub>3</sub> + Al<sub>2</sub>O<sub>3</sub> 1.7 - 2.0%, CaO 0.3%, MgO 0.2%, and volatile matter 1.5%; calcn. gave 85% SiO and 10.5% SiO<sub>2</sub> in agreement with vapor pressure and optical-crystallographic data ( $n \approx 2.0$ ). The gas phase first liquified and then formed the solid. Specimens of fume collected in 1-3 min. on Ni gauze were examd. in a magnetic electron microscope. The spherical particles observed varied in size from 1  $\mu$  to 40  $\mu$ , or less and were comparable to synthetic SiO particles. A. G. Guy

Text Data

Coverage: This volume is an exhaustive treatise on reactions between  
gaseous and solid phases in metallurgical processes. Each particular  
pyrometallurgical reaction is analysed from two points of view: the  
thermodynamic analysis is given first, and then the mechanism and  
kinetics of the process are discussed. Among the large variety of  
pyrometallurgical reactions the following were selected: (1) com-  
bustion of solid and gaseous fuels, (2) dissociation of oxides,

Slags containing SiO<sub>2</sub>. P. V. Gel'd and O. A. Esin (S. M. Kirov Ural Polytech. Inst.). *Doklady Akad. Nauk S.S.S.R.* 70, 473-4 (1950).—Chem. analysis of many slags formed in smelting 45-75% ferrosilicon, silicocalcium, silicozirconium, Si, C-free ferrochrome, and other alloys, shows that, if all Si is in form of SiO<sub>2</sub>, the total sum is over 100%, in some cases reaching 120-130%. The presence of metal beads in slag cannot account for this large difference. Electron-microscope study of chimney deposits and sublimate shows that they consist of spherical particles formed as a result of the oxidation of SiO<sub>2</sub> fog. Vitreous condition of the deposits, their compn. (up to 85% SiO<sub>2</sub>), and spherical form of particles indicate that condensation of SiO<sub>2</sub> proceeds through the preliminary formation of a liquid phase rich in SiO<sub>2</sub>. This is confirmed by a study of the slag obtained in smelting 75% ferrosilicon. The slag consisted of an outer layer (compn. calcd. on the basis of all Si as SiO<sub>2</sub>: SiO<sub>2</sub> 120.20, Al<sub>2</sub>O<sub>3</sub> 1.45, FeO 0.39, CaO 0.63, and MgO 1.36%) and an inner layer (SiO<sub>2</sub> 82.50, Al<sub>2</sub>O<sub>3</sub> 10.79, FeO 1.36, CaO 12.04, and MgO 3.36%); this would give a min. of 80.22% SiO<sub>2</sub> for one and 19.08% SiO<sub>2</sub> for the other. Immersion study indicates that a considerable portion of the inner layer consists of crystals with  $n$  of about 2.0 which is

close to synthetic SiO<sub>2</sub>. Besides, it contains colorless glass with low  $n$  and  $\beta$ -cristobalite. The outer layer was shown by x-rays to consist of spherical particles of Si cemented with a dark material similar to that of the inner layer. The size of Si globules increases regularly from the outer surface to the boundary of the layers. Globules of Si did not exist in the mother liquid phase but appeared during its cooling in accordance with  $2SiO_2 = Si + SiO_2$ ; their distribution along the depth of the layer is governed by the conditions of cooling. Conclusions: Liquid slags exist which contain silico-oxygen compds. and Si atoms are partially united to one another directly and partially through O atoms. During their reaction with easily reducible oxides (FeO, MnO), metal is formed and there is an increase in the no. of bonds through O atoms. Thus, the concn. of FeO and MnO in such slags is not great. In the presence of difficultly reducible oxides (MgO, CaO), the complexes attach O ions and are ruptured along the bonds Si—O—Si and the ions  $Me^{2+}$  do not change into metal. B. Z. Kamich

CA

Thermodynamic analysis of the equilibrium conditions in the reduction of iron chromite by carbon. P. V. Gel'd and O. A. Rein (S. M. Kirov Ural Polytech. Inst., Sverdlovsk). *Zhur. Priklad. Khim.* (J. Applied Chem.) 23, 1360-70 (1950). (1) At any temp. between 500 and 950°, a continuous increase with time of the pressure of CO is observed in the system  $\text{FeCr}_2\text{O}_4 + \text{C}$  (graphite), i.e. establishment of equil. is very slow, and equil. cannot be reached and detd. experimentally. In this respect, chromite be-

haves like dolomite, and the reason for the slowness in attainment of equil. is that one of the 2 components,  $\text{FeO}$ , is reduced by C much more easily, and earlier, than  $\text{Cr}_2\text{O}_3$ . (2) On account of the difficulty of exptl. realization of the equil.  $\text{FeCr}_2\text{O}_4 + 4\text{C} = \text{Fe} + 2\text{Cr} + 4\text{CO}$ , the thermodynamic data for its 2 consecutive steps, (a)  $\text{FeCr}_2\text{O}_4 + \text{C} = \text{Fe} + \text{CO} + \text{Cr}_2\text{O}_3$ , and (b)  $\text{Cr}_2\text{O}_3 + 3\text{C} = 2\text{Cr} + 3\text{CO}$ , were calcd. From the known empirical equations for the heat capacities of the substances involved, one has, for (a)  $\Delta H^\circ = 0.483 T - 0.774 \times 10^{-4} T^2 + 8.053 \times 10^5 / T$ . From other thermodynam. literature data,  $\Delta H^\circ = 50,874 \text{ cal}$ , and hence  $\Delta F^\circ = 50,874 + 0.483 T \ln T + 0.774 \times 10^{-4} T^2 - 2.751 \times 10^5 T^{-1} + 37.714 T$ , and  $\log K_p \sim \log p_{\text{CO}} = -(11.112/T) - 0.246 \log T - 0.17 \times 10^{-4} T + 0.6 \times 10^5 T^{-1} + 9.597$ , or, simplified,  $\log p_{\text{CO}} = -(10,403/T) + 8.053$ ; numerically, at 800, 1000, 1200, 1400, 1600°K.,  $\log p_{\text{CO}} = -4.987, -0.353, -0.817, +0.621, 1.553, 2.273$ . The actually observed pressures of CO, even though equil. was not even remotely attained, were very much higher than the thermodynamic equil. pressures; thus, at 720°C.,  $\log p_{\text{CO}}$  (exptl.) = -0.65 (calcd.) = -2.42. The deviations decrease with rising temp. but still remain major. They may be caused by the presence of easily reducible impurities.

*over*

exptl. plot shows  $1/\delta$  to be a linear function of  $1/\sqrt{\delta}$  up to  $\delta = 10^{-4}$  sec., i.e. the same law applies to  $\delta$  as to the depth of penetration of the magnetic field ("normal" skin effect). However, above  $\delta = 10^{-4}$ ,  $\delta$  decreases at a faster rate ("anomalous" skin effect), evidently as a result of adiabatic inhibition effects. Points taken at 3.300° and at 3.020° K. lie on the same curve. On the assumption that at the transition takes place within a time interval not over  $1/2$  of the period  $T$  of the a.c., one finds  $v > \delta/(T/2)$ , and, with  $\delta \sim 3 \times 10^{-4}$  cm. at  $T = 10^{-4}$  sec.,  $v > 3 \times 10^4$  cm/sec. These experiments were done under nearly adiabatic conditions, and as the temp. changes accompanying the transition, cause a variation of  $H_c$ , which is greater upon disturbance than upon restoration of the supercond. Furthermore, whereas the transition from normal state to supercond. proceed rapidly through displacement of the boundary, restoration, through production and growth of nuclei, may proceed considerably slower. This was confirmed by applying, to a sample in the superconductive state, a field  $H = H_c + H_0$ , i.e. a const. field of  $H_c$  superposed on an alternating field  $H_0$ . At  $H$  only slightly in excess of  $H_c(T)$ , not all the vol. of the sample goes over into the normal state, as the fall of temp. resulting from partial transition will raise  $H_c(T)$  and put a stop to further transformation at the given  $H$ . Complete disturbance of the supercond. is attained only with a field  $H = H_c$  sufficient for the elimination of the supercond. at any temp.  $T$ , which may be reached in the adiabatic transition. Evidently,  $H_c(T_1) > H_c(T_2)$ , and, similarly, for the transition from normal to supercond.,  $H_c(T_1) < H_c(T_2)$ . Plots of  $H_c$  as a function of  $T$  obtained for the adiabatic transitions in either direction give, for each  $T$ , the max. and the min. temp. attained by the sample in the process of the transition, and these limits agree with thermodynamic values. The causes of the high velocity of the displacement of the boundary, measured in an alternating magnetic field, as compared with the much smaller velocity of disturbance of the superconducting state in stationary magnetic fields, are seen in the different rates of heat transfer, and in electrodynamic effects linked with Foucault currents. N. T.

2

Kinetics of the reduction of chromium oxide and of iron chromite. P. V. Gel'd and O. A. Bain (S. M. Kirov Ural Polytech. Inst., Sverdlovsk). *Zhurn. Priklad. Khim.* (J. Applied Chem.) 23, 1271-6 (1950).—(1) Data of Baukloh and Henke (*C.A.* 32, 2044) on the rate of reduction of  $\text{Cr}_2\text{O}_3$  with  $\text{H}_2$  can be represented by  $\log A = (30,000/4.575 T) + B$ , where  $A = \%$  of reduction of  $\text{Cr}_2\text{O}_3$ . The activation energy  $E = 30,000$  cal./mole is independent of  $A$ . The coeff.  $B$  varies with time  $\tau$  (hrs.) according to  $B = \log (177 \times 10^3 \tau - 4.575 \times 10^3 \tau^2 + 0.400 \times 10^3 \tau^3)$ , i.e. in the manner characteristic of topochem. processes with simultaneous start of the reaction over the whole surface. (2) Exptl. kinetic detns. of the reduction of  $\text{Cr}_2\text{O}_3$  mixed with graphite (100% excess) in pellets pressed under 100 kg./sq. cm., were run, by loss of wt., at 1150, 1175, 1250,

and 1300°. No reaction is observed at 1100°, but is perfectly measurable at 1150°. Reduction with C is considerably faster than with  $\text{H}_2$ . (3) Under the same conditions, chromite ore ( $\text{Cr}_2\text{O}_3$  63.14,  $\text{FeO}$  12.2,  $\text{MgO}$  12.37,  $\text{Al}_2\text{O}_3$  13.44,  $\text{SiO}_2$  6.28%) is reduced by graphite more slowly than pure  $\text{Cr}_2\text{O}_3$ , despite the greater thermodynamic ease of reduction of the chromite ore. This contradiction is attributed to binding of  $\text{Cr}_2\text{O}_3$  particularly by  $\text{MgO}$ , the Mg chromite being less easily reducible than  $\text{Cr}_2\text{O}_3$ . Communion of the ore facilitates greatly its reduction with C, and so does admn. of 3%  $\text{K}_2\text{CO}_3$ .

Method of measurement of the interfacial tension at high temperatures. S. I. Popel, O. A. Ekin, and P. V. Gol'd (S. M. Kirov Ural Polytech. Inst., Sverdlovsk). *Doklady Akad. Nauk S.S.S.R.* 74, 1097-1100(1960).—The interfacial tension  $\delta$  is detd. from the height  $h$  (measured from the top to the equator of the drop) of a drop, photographed with x-rays, which permits photography of a drop of metal (15-25 mm.) in a fused slag. With  $\rho_1$  and  $\rho_2 = d.$  of the metal and of the medium, resp.,  $\delta = \frac{1}{2}(\rho_1 - \rho_2)gh^2$ , where  $g$  = acceleration of gravity. The method was applied to drops of Hg (against air and against  $H_2O$ , at  $20^\circ$ ), of Cu (against gas, at  $1300^\circ$ ), and of cast iron (against gas, at  $1400^\circ$ ). It gives generally too low values of  $\delta$  as compared with detns. with the aid of other equations, but close thereto. Frozen drops generally show  $h$  smaller by about 10% than in the molten state, which may give rise to deviations in  $\delta$  of ~14-22% with the ds. taken as those of the solids, and of ~5-20% with the use of the ds. of the fused substances. Consequently,  $\delta$  ought to be detd. in the

liquid state. The method is indicated for chemically aggressive or highly viscous substances.

C.A.

Effect of salts on the rates of dissociation and reduction processes. P. V. Gel'd and O. A. Egin (S. M. Kirov Ural Polytech. Inst., Sverdlovsk). *Doklady Akad. Nauk S.S.S.R.* 73, 541-4 (1960).—The rate of the reduction of chromite,  $\text{FeO} \cdot \text{Cr}_2\text{O}_3$ , by  $\text{H}_2$  or C (graphite) to  $\text{Fe} + \text{Cr}_2\text{O}_3 + \text{H}_2\text{O}$  (or CO) measured by the amt. reduced in 1 hr. at const. temp., between 300 and 1200°, is strongly accelerated by the addn. of 3%  $\text{K}_2\text{CO}_3$ . Rupts. remained far below the equil., which cannot be reached even in 15 hrs. Reduction by C is faster than by  $\text{H}_2$ . The disasn.  $\text{CaC}_2 \rightarrow 2\text{C} + \text{Ca}$  (vapor), very slow at 1200°, is markedly accelerated by 5%  $\text{CaF}_2$  or  $\text{CaCl}_2$ , and even more by 5%  $\text{BaCl}_2$ . At 1300°, the order of increasing accelerating effectiveness is 5%  $\text{CaF}_2$ ,  $\text{CaCl}_2$ ,  $\text{K}_2\text{CO}_3$ ,  $\text{NaCl}$ . Halides of alkali metals should be more effective than alk. earth metals, but they evap. at these temps. The effect is interpreted as an accelerating action of the anions of the salt on the mobility of the cations involved in the reconstruction of the solid lattice. N. T.

**Interphase tension of iron alloys at the slag interface**  
S. I. Popel, O. A. Kozin, and P. V. Gel'd (S. M. Kirov Ural Polytech. Inst., Sverdlovsk). *Doklady Akad. Nauk S.S.S.R.* 75, 227-30(1980); cf. C.A. 45, 27434.—A previously described method was used to det. the interphase tension between molten Fe alloys and slags. A pig iron contg. C 3.45, Si 2.21, Mn 0.64, P 0.263, and S 0.105% had at 1420° a surface tension with gas of 1022 erg./sq. cm. and interphase tensions of about 630, 700, and 750 erg./sq. cm. with slags contg. 0, 14, and 30% Al<sub>2</sub>O<sub>3</sub> (plus 47% CaO, balance SiO<sub>2</sub>). A synthetic Fe alloy contg. 4.0% C and 0.4% S had at 1480 to 1530° a surface tension with gas of 675 and interphase tensions of about 350, 600, and 610 with slags contg. 16, 27, and 39% CaO (plus 26% Al<sub>2</sub>O<sub>3</sub>, balance SiO<sub>2</sub>). When Na<sub>2</sub>O replaced about 5% of the CaO in the 39% CaO slag, the interphase tension at 1400° dropped to about 500, and when Na<sub>2</sub>O completely replaced the CaO the value became 410. A synthetic slag contg. SiO<sub>2</sub> 48, CaO 26, and Al<sub>2</sub>O<sub>3</sub> 26% had at 1420 to 1510° interphase tensions of about 600, 610, 480, and 280 with Fe alloys contg. Si 0.4, C 4.8; Si 8.0, C 2.8; Si 31, C 2.6; Si 40, C 0.2%. The results are explained by the ionic theory of slags on the basis that cations and anions of the slag which have a large ratio of charge to radius will strongly adhere to each other and displace ions with weak fields from the surface layer. "Effect of Carbon on the Interphase Tension of Iron at the Boundary With Slag," S. I. Fogel', O. A. Yesin, Yu. P. Nikitin, Ural Polytech Inst Invent S. M. Kirov, Sverdlovsk

"Dok Ak Nauk SSSR" Vol LXXXIII, No 2, pp 253-255

Describes expts for detg interphase tension of a number of iron-carbon alloys at boundary with slag in range of 1,450-1,500°, using method of resting drop in combination with X-raying. Since existing integral formulas for approximating interphase or surface tension are too complicated and give

214766

greatly divergent results, more convenient and sufficiently precise calg method of graphical integration was employed. Submitted by Acad A. N. Frumkin 10 Jan 52.

**Electrocapillary phenomena at high temperatures.** O. A. Esin, Yu. P. Nikitin, and S. I. Popel (Ural Polytech. Inst., Sverdlovsk). *Doklady Akad. Nauk S.S.S.R.* 83, 431-4 (1982). The surface tension of molten Fe-C alloys with 2.5, 3, and 4% C, in a fused-silicate electrolyte of the compn.  $\text{SiO}_2$  71.5,  $\text{Na}_2\text{O}$  14.6,  $\text{CaO}$  8.3,  $\text{Al}_2\text{O}_3$  5.6% was measured as a function of the polarization by the drop method. The diam. of the drop was 14-16 mm., and the surface area of the other electrode, a graphite tube, large enough to be considered nonpolarizable. The e.d. was not over 50  $\text{m}^2/\text{sq. cm.}$  In the temp. range 1420-1480°, the interface tension  $\sigma$  decreases with increasing neg. polarization  $\phi$ . These exptl. curves represent the cathodic branches of the electrocapillary curves. Anodic polarization has less effect on  $\sigma$  than does cathodic polarization. Consequently, the  $\text{Na}^+$  ions are more surface-active than the silicate anions. The curves of  $\sigma$  are steeper at lower C contents of the metal. The charge d.  $-E = d\sigma/d\phi$ , between 0 and -0.2 v., is 50 and 30 microcoulombs/sq. cm. with 2.5 and 4% C, resp. It follows that the adsorption of C at the surface of the drop falls with increasingly neg.  $\phi$ ; i.e. the pos. charge of the double layer on the electrolyte side repels from the metal surface the C cations more strongly than it repels the Fe cations. N. Thon

✓ The properties of liquid iron-chromium alloys by the method of electromotive forces. O. A. Esin and N. A. Vatulov. *Izvest. Akad. Nauk S.S.S.R., Otdel. Tekh. Nauk* 1953, 1137-42.—The values of e.m.f. at 1460° in a concn. system consisting of 2 alloys of Fe with C and Cr of various compns. and with slag of CaO, MgO, SiO<sub>2</sub>, and CrO were detd. The Cr concn. ranged from 1.08% to 27.5%; the C content was that of a satd. alloy. The e.m.f. detns. were used to calc. the free energy in transfer of Cr from the more concd. to the more dil. system, and coeffs. of activity of Cr and Fe were calcd. E.m.f. detns. were made in a system (at 1400°) whose electrodes were alloys of Fe with Cr and Si satd. with C, while CaO, MgO, and SiO<sub>2</sub> slag was used as the electrolyte. The Cr concn. was varied from 3% to 60%, and the Fe-Cr ratio was held near unity. The curves of dependence of e.m.f. on the concn. of Si shows 2 inflections, indicating the existence of at. groupings of silicides (Fe, Cr)Si and (Fe, Cr)Si<sub>2</sub>. The result agrees with the existence of 2 breaks in the soly. curve of C in ferro-chromium.

✓ Forms of silica existing in molten slag. O. A. Egan, L. R. Garverdy, and B. M. Lazubskikh (C.R. Acad. Sci., 28, 713-716).—The e.m.f. of a concentration cell without transference, consisting of two Fe-Si electrodes each in contact with molten slag of different composition separated by a magnesite or graphite diaphragm, is determined at 1470° as a function of  $\text{SiO}_2$  content in one half-cell. There are two breaks on the obtained curve, corresponding to 33 and 53 wt.-%  $\text{SiO}_2$  in the slag. In the first part of the curve (up to 33%  $\text{SiO}_2$ )  $\text{SiO}_2$  exists as  $\text{SiO}_4^{4-}$  anions, in the second mainly as  $\text{SiO}_4^{4-}$  and  $(\text{SiO}_3)^{3-}$ , and in the third as  $(\text{SiO}_2)_n$  and in the form of little known  $\text{Si}_2\text{O}_7^{6-}$  complexes. Title : Structure of glasses and the properties of melted silicates

Periodical : Stek. 1 ker. 11/3, 4-6, Mar 1954

Abstract : An account is given of researches conducted by many scientists to ascertain the crystalline structure of glass and the properties of melted silicates. These involved variations of temperature, chemical composition of various glasses, reaction to electrical currents, examination of crystalline structure by X-rays and refraction effects. The structure of glass was found to be similar to that of a supercooled liquid.

"The Surface Activity of Carbon and Phosphorus at the Metal-Slag Interface"

Tr. Ural'skogo Politekhn. In-ta, sb. 49, 1954, 82-86

Interfacial tension of iron-carbon and iron-phosphorus alloys with synthetic slag was determined by photographing drops lying on a corundum block and correlating the results with X-ray data. Established that as the carbon and phosphorus content is increased, the interfacial tension is decreased. The effect of phosphorus is less than that of carbon. Interfacial tension of above alloys is close to that of the surface tension of iron-carbon alloy with carbide slag was estimated using the cooled drop method, and found to be less than the surface tension of the slag. (RZhKhim, No 3, 1955)

"Investigation of the Physicochemical Properties of the System  $\text{FeO-SiO}_2$ ".  
Tr. Ural'skovo Politekh. In-ta, No. 49, pp 104-124, 1954.

Measured the viscosity, electric conductivity, surface tension, and density of liquid melts of the system  $\text{FeO-SiO}_2$ . Viscosity was measured using two methods, i.e., the method of coaxial cylinders or optic measurement of the angle of rotation of a thread, with the application of the method of damped oscillations. Electric conductivity was measured using an iron crucible and iron rods, both acting as electrodes. Surface tension was determined using the bubble method.

SO: Sum No 884, 9 Apr 1956

Electrolysis of fused iron slags. O. A. Esin and P. M. Shurzhuk (S. M. Kirov Inst. Metall., 1965). Dzh. Akad. Nauk S.S.S.R. 64, 1145-7 (1964). The great esp. difficulties of direct electrolysis of Fe-silica slags with electrodes of graphite or Fe are discussed by author Esin in the cathode material, which is also discussed by the Fe metal. The anode is applied in Fe-silica Ca-Mg-Al slags, while a current of pure Fe washes the electrode to avoid the spontaneous reaction  $Fe^{2+} + e \rightarrow Fe^+$  in the melt. The expts. are made at 1350° to 1400° in a C resistor furnace, with a c.d. of 0.2-3.5 amp./sq. cm. The electrolytic output (in g.d. of the theory) are plotted as a function of the oxidation degree of the slag given by the ratio  $\frac{Fe^{2+}}{Fe^{3+} + Fe^{2+}}$ . The cath. slag melts have a compn. of the system  $FeO-Fe_2O_3-SiO_2$ , with  $SiO_2$  varying between 6 and 44%. The oxidation degree is decreased with increasing  $SiO_2$  content. An increase in the degree of acidity of the slag from 6 to 44% brings about a decrease in the output from 82.6 to 10.7. Slags of the system  $FeO-Fe_2O_3-CaO-SiO_2$  (CaO 1-40%) show much higher outputs than the corresponding CaO-free melts, even for 39 to 35%  $SiO_2$ , while slags of the system  $FeO-Fe_2O_3$  never show outputs above 35%. This latter fact is in contradiction to the opinions of Fischer and Balle (C.A. 44, 16423, 45, 3423) that pure Fe oxide slags would not be able to show any electrolysis. A slag with 40%  $(FeO + Fe_2O_3)$ , 20%  $Al_2O_3$ , and 40%  $SiO_2$  shows a surprisingly good output (22% to 6.5%) in spite of the high acidity. The very different slopes of the electrolysis curves also indicate the high influence of viscosity in the melts on the regeneration of  $Fe^{2+}$  ions by convection and diffusion from the furnace atm. The elec. cond. of Fe-silicate slags is, however, not exclusively electrolytic; it is in some part electronic. Therefore, a diln. of the Fe oxides by addns. of  $SiO_2$ ,  $CaO$ , and  $Al_2O_3$  to the melts brings about a reduction of the electronic share of the cond. and an increased electrolytic output. W. Ertl.

Title: Structural Specific Features of Vitreous and Liquid Silicates

Original

Publication: Sb. Stroyeniye stekla, M.-L., AN SSSR, 1955, 44-45

Abstract: Experimental data confirm not only the microheterogeneity and certain orderliness of glasses, but also their ionic nature (on formation from basic and acidic oxides). Glasses are incorrectly designated as microheterogeneous systems since one should not identify crystallites, which are merely micro-regions of heterogeneities with incipient orderliness, with crystals, that have long-range order and interfaces. A crystallite is the embryo of a crystal. Growth of a crystallite, that leads to its gradual conversion to a crystal, is not a simple quantitative change but a complex process of enhancement

Title : ~~Research work~~  
A study on the kinetics of dephosphorization of liquid iron by slag

Periodical : Izv. AN. SSSR, Otd. Tekh. Nauk, 3, 79-89, March 1955

Abstract : Describes the methodology of the experiment conducted and analyzes the findings. The study brought out the fact that the speed with which dephosphorization takes place depends on the chemical reaction of the phosphorous with the slag, rather than on convection and thus physical exposure of the phosphorous to the slag. The area of contact between the slag and the iron and not the height of the slag layer influences dephosphorization. The hypothesis is proposed that the stage which determines the speed of the reaction of phosphorization, is the desorption of the anion ( $\text{PO}_4^{3-}$ ) at the slag-to-metal surface. G. E. H. W.

The form of gamma in fused slags. C. A. Esin and R. A. Gerasimov, *Zhurnal Fizicheskoi Khimii*, 1964, 38, 1173-1175. English transl. in *Chem. Abstr.*, 1964, 58, 1173. The authors study the form of gamma in complex silicates and oxides. The authors measured the electromotive force of the cell: Pt, Al, CaO, MgO, Al<sub>2</sub>O<sub>3</sub>, SiO<sub>2</sub> (concn. 1), C/CaO, MgO, Al<sub>2</sub>O<sub>3</sub>, SiO<sub>2</sub> (concn. 11)/Pt, Al, C. The e.m.f. of such cell is determined by the ratio of the activities (a) of Al<sub>2</sub>O<sub>3</sub> and SiO<sub>2</sub> in the melt:  $E = (RT/6F) \ln(a_{Al_2O_3}/a_{SiO_2})$ . The e.m.f. were made at the const. temp. of 1450° in a graphite crucible. The e.m.f. plotted as the concn. of Al<sub>2</sub>O<sub>3</sub> shows two discontinuities which correspond to the transitions of complex anions derived from  $6CaO \cdot 3Al_2O_3$  and  $2CaO \cdot Al_2O_3 \cdot SiO_2$ . A peculiar third discontinuity is explained as an indication of the amphoteric character of Al<sub>2</sub>O<sub>3</sub>. Given of const. e.m.f. are plotted in the system CaO-Al<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> which shows distinctly a field in which Al forms the cation Al<sup>3+</sup> (if the melts are rich in Al<sub>2</sub>O<sub>3</sub> and SiO<sub>2</sub>), and another field (for melts high in CaO) in which Al enters the complex anions. Also in *Doklady Akad. Nauk SSSR*, 94, 1187-90 (1964). W. E. H.

Title : Mechanism of desulfurization of cast iron

Periodical : Dok. AN SSSR 101/6, 1065 - 1067, Apr. 21, 1955

Abstract : Experiments were conducted with the aid of radioactive Fe<sup>59</sup> isotope to confirm whether the iron which appears in slag together with sulfur is in the form of small metal beads (ejected by the forming gases) or in the form of FeS molecules. Tests with graphite and magnesia crucibles showed that more sulfur penetrates into the slag than iron but the FeS and S<sup>2-</sup> molecule concentrations are equal. The process of desulfurization is explained. It is pointed out that the acceleration of desulfurization of iron is mainly due to the formation of calcium carbide in the slag. references: 2 USSR and 2 USA (1948-1952). Table; diagram.

Title : The kinetics of sulfur distribution between liquid iron and slag

Periodical : Dok. AN SSSR 102/3, 583 - 586, May 21, 1955

Abstract : Experiments were conducted with technically pure Fe containing 0.05% C, 0.003 Si, 0.003 P and 0.004 S and three types of slag of different basicity at temperatures of 1550 - 1700° to determine the kinetics of S-distribution between the melted iron and the slag. The introduction of S<sup>35</sup> and Fe<sup>59</sup> isotopes into the metal made it possible to determine the kinetics of the iron with acid slag (at 1550°) and the kinetics of the iron with basic slag (at 1600°) and the kinetics of the conversion of large quantities into basic or neutral slag (at 1560°) accompanied (at 1560°) by an increase in Fe content in the slag. Soveshchaniya po eksperimental'noy tekhnike i metodam vysokotemperaturnykh issledovaniy, 1956

Eksperimental'naya tekhnika i metody issledovaniy pri vysokikh temperaturakh; trudy soveshchaniya (Experimental Techniques and Methods of Investigation at High Temperatures; Transactions of the Conference on Experimental Techniques and Methods of Investigation at High Temperatures) Moscow, AN SSSR, 1959. 789 p. (Series: Akademiya nauk SSSR. Institut metallurgii. Komissiya po fiziko-khimicheskim osnovam proizvodstva stali) 2,200 copies printed.

Resp. Ed.: A.M. Samarin, Corresponding Member, USSR Academy of Sciences; Ed. of Publishing House: A.L. Bankovits.

PURPOSE: This book is intended for metallurgists and metallurgical engineers.

COVERAGE: This collection of scientific papers is divided into six parts: 1) thermodynamic activity and kinetics of high-temperature processes 2) constitution diagram studies 3) physical properties of liquid metals and slags 4) new analytical methods and production of pure metals 5) pyrometry, and 6) general questions. For more specific coverage, see Table of Contents.

Yefin, M.A., and O.A. Yefin. Solubility of Carbon in Iron Alloyed With Various Elements 88

A study was made of the effect of phosphorus, chromium, manganese, sulfur, and vanadium on the solubility of carbon in liquid iron, and also of silicon on the solubility of carbon in molten manganese and ferrochrome. It was shown that regularities observed in the effect of the nature and concentration of the addition, as well as of the temperature, can be qualitatively explained with the aid of the theory of regular solutions.

Ivanov, L.I., I.S. Kulikov, and M.P. Matveyeva. Methods of Measuring the Thermodynamic Constants of Metals and Alloys at High Temperature 96

An apparently reliable method was developed for determining the heat of sublimation of metals, making use of the principle of isotope exchange in the gaseous phase of metals.

The use of radioactive isotopes permits the determination of partial values of the following thermodynamic constants: rate of vaporization, vapor pressure, heat of sublimation, and the individual thermodynamic activity of each of the elements of the alloy.

Shchedrin, V.M. Stand for Studying High-Temperature Reduction Processes Under Pressure 131

Brubor, R.A., and V.V. Gol'd. Rate of Hydrogen Diffusion in Steels at High Temperatures 147

The rate of diffusion at a given temperature was determined on the basis of the quantity of hydrogen diffusing per unit time through a unit section of fixed thickness, as measured by the drop in pressure. The effect of alloying elements (carbon, chromium, vanadium, silicon, manganese, and nickel), decomposition of austenite, and pressure on the rate of diffusion were studied.

**III. PHYSICAL PROPERTIES OF LIQUID METALS AND SLAGS**  
Popel', S. P., and O. A. Yezhin. Methods of Measuring the Surface  
Tension of Liquid Metals and Slags 257  
A comparison was made of the results obtained in measuring  
the surface tension of slags of the systems  $\text{CaO-SiO}_2\text{-Al}_2\text{O}_3$   
and  $\text{CaO-SiO}_2\text{-MgO}$  by the maximum-bubble-pressure method and  
the sessile-drop method. It was shown that the replacement  
of  $\text{SiO}_2$  by  $\text{CaO}$  (with constant  $\text{Al}_2\text{O}_3$  content) in the system  
 $\text{CaO-SiO}_2\text{-Al}_2\text{O}_3$  leads to an increase in surface tension. An  
increase in the content of  $\text{Al}_2\text{O}_3$  (with a constant ratio of  
 $\text{CaO}$  to  $\text{SiO}_2$ ) also results in higher surface tension. This is  
explained by a breaking-down of silicate anions. It was  
shown that the replacement of  $\text{CaO}$  by  $\text{MgO}$  in the system  
 $\text{CaO-SiO}_2\text{-MgO}$  has practically no effect on surface tension.

Korol'kov, A.M. Surface Tension and Fluidity of Aluminum- and Zinc-Base Alloys  
No direct relationship between surface tension and fluidity of the alloys investigated was observed. 269

Xoravskiy, V.M., Yu.M. Ivashchenko, and V.I. Mizhenko.  
Measurement of Surface Tension of Metals and Alloys by the sessile-drop method  
The surface tension of tin at temperatures of 251-330°C was determined by the sessile-drop method and the maximum-bubble-pressure method. The former method was shown to be accurate to within 4-5 percent and capable of further refinement with improved equipment and methods of calculation. 285

Lapinskikh, B.M., and G.A. Yezlin. Measurement of the Electrical Conductivity of Immiscible Slags  
Measurements were made of the electrical conductivity of the systems  $MgO-TiO_2$ ,  $FeO-TiO_2$ , and  $MnO-TiO_2$  of various Card 12/32 295

compositions and at various temperatures using a Wheatstone bridge and a weak alternating current. The conductivity of these systems falls with an increase in  $TiO_2$  content; as in the case of silicate systems. Results indicate that conductivity is higher in the  $MnO-TiO_2$  system than in the  $FeO-TiO_2$  system, that in both of these systems it is higher than in the  $MnO-SiO_2$  and  $FeO-SiO_2$  systems, and that in the  $MgO-TiO_2$  system it is lower than in the  $MgO-SiO_2$  system.

Title : On Kinetics of Silicon-Reduction Process

Orig Pub : Izv. AN SSSR, Otd. tekhn. n., 1956, No 6, 113-118

Abstract : Study of kinetics of the reduction of silicon with liquid iron in slag  $MO - Al_2O_3 - SiO_2$ , saturated with  $SiO_2$ . Rate of the process is determined from the amount of radioisotope  $Fe^{59}$ , that passes from Fe into the slag as  $Fe^{2+}$ . Depth of slag layer does not affect rate of reaction, i.e., complications due to diffusion are apparently absent. Reduction rate decreases greatly on replacement of  $MgO$ , in the slag, by  $CaO$  or  $BaO$ . Determined were the apparent energies of activation for slags of different composition: with 64.4%  $SiO_2$  + 32.1%  $MgO$  (at 1560-1660°) 51 kcal; with 61.2%  $SiO_2$  + 19.4%  $CaO$  + 17.4%  $Al_2O_3$  (at 1580-1620°) 66.5 kcal; with 59.1%  $SiO_2$  + 37.3%  $BaO$  (at 1580-1680°) 148 kcal. It is assumed that effect of cations on rate of process is due to different degree of weakening of bonds between Si and O atoms in the slag.

Title : Electrochemistry of molten oxides (Review)

Periodical : Zhur. fiz. khim. 30/1, 3-19, Jan 1956

Abstract : The bases for experimental electrochemistry are reviewed with respect to molten metallurgical slags such as silicates, aluminosilicates, ferrites, titanates, etc. Data are presented regarding the specific electroconductivity of molten oxides and their thermal coefficients. The thermal conductivity coefficient of  $\text{Fe}_2\text{O}_3$  melt was found to be positive. The electroconductivity of molten oxides of elements of different valence is discussed. Sixty references are given. 7 Germ., 3 Eng., 2 Japan. and 12 USA (1927-1955). Graphs.

Title : Electrode Polarization in Fused Silicates and Formation of Divalent Silicon

Orig Pub : Zh. fiz. khimii, 1956, 30, No 2, 374-378

Abstract : Determination of electrode polarization in silicate slags (43% SiO, 46% CaO, 10% MgO, remainder phosphides) at 1490-1610°, by the commutator method. Liquid ferro-phosphorus (23% P) was used as the electrode. On comparing the results obtained with previous determinations (RZhKhim, 1956, 12533, 12534), the authors arrive at the conclusion that polarization in fused silicates exhibits the same regularities as in the case of the use of FeSi electrodes. It is shown that the cause of polarization can be not only slowed down deformation and orientation of complex silicon-oxygen anions but also an accumulation

Title : Surface Tension of the Simplest Oxide Systems

Orig Pub: Zh. Fiz. Khimii, 1956, Vol 30, No 6, 1193-1201 (with English  
summary)

Abstract: The bubble-pressure method was used to investigate the surface  
tension ( $\sigma$ ) of the systems: FeO-Fe<sub>2</sub>O<sub>3</sub> (I), FeO-Fe<sub>2</sub>O<sub>3</sub>-SiO<sub>2</sub> (II),  
FeO-SiO<sub>2</sub>-MnO (III), FeO-CaO-Fe<sub>2</sub>O<sub>3</sub> (IV), FeO-Na<sub>2</sub>O-Fe<sub>2</sub>O<sub>3</sub> (V) and  
FeO-CaO-SiO<sub>2</sub> at 1300-1400° in an atmosphere of nitrogen. It is  
shown that FeO is the surface active component in all the investi-  
gated systems ( $\sigma$  at an Fe<sub>2</sub>O<sub>3</sub> content of ~3 atom percent is equal  
to ~590 ergs/cm<sup>2</sup>). Fe<sub>2</sub>O<sub>3</sub> is surface active in I and reduces  $\sigma$  at  
a content of 15.1% to 490 ergs/cm<sup>2</sup>. Calculation of a Gibbs adsorp-  
tion isotherm (G) for Fe<sub>2</sub>O<sub>3</sub> gives  $G_{\max} = 0.8 \times 10^{-9}$  mole/cm<sup>2</sup>. A

Title : Electro-Osmotic Phenomena in Pyrometallurgical Systems

Orig Pub: Dokl. AN SSSR, 1956, Vol 107, No 6, 847-849

Abstract: A method previously described by the authors (Dokl. AN SSSR, 1952, Vol 83, 341) was used to obtain electroosmotic curves for Ni sulfides (96.1% Ni<sub>3</sub>S<sub>2</sub> and 3.9% Ni), Cu sulfides (77.7% Cu, 1.3% Fe, and 20.5% S) at 1,350-1,400° as well as for an Mn-C alloy (7% C, 0.14% Si, 0.37% P, 0.007% S) at 1,480-1,500°. It has been established that in the absence of an external electric field the surface of the melts in contact with the slag is charged negatively. The density of this charge ( $\epsilon$ ), calculated from the equation  $(\partial \sigma / \partial \varphi) = - \epsilon$ , at  $\varphi = 0$  is  $15 \times 10^{-6}$  coulombs/cm<sup>2</sup> for Ni sulfide; for Cu sulfide and the Mn-C alloy the density is  $12 \times 10^{-6}$  and  $9 \times 10^{-6}$  coulombs/cm<sup>2</sup>, respectively. A method based on the measurement of the flow which arises

PHASE I BOOK EXPLOITATION

306

Gel'd, Pavel Vladimirovich, and Yesin, Oleg Alekseyevich

Protsessy vysokotemperaturnogo vosstanovleniya (Processes of High-temperature Metal Reduction) Sverdlovsk, Metallurgizdat, 1957. 646 p. 4,500 copies printed.

Ed.: Yur'yev, B.N.; Ed. of Publishing House: Kel'nik, V.P.:  
Tech. Ed.: Zef, Ye.M.

PURPOSE: This book is intended for metallurgists and metallurgical engineers, as well as for vtuz students taking advanced courses in metallurgy.

COVERAGE: The authors state that until recently the attention of physical chemists working in the field of oxide reduction was focused mainly on studying the mechanism and kinetics of the indirect reduction of comparatively unstable oxides of iron, nickel, copper, manganese, etc. Direct reduction has been studied much less extensively, especially the reduction of such oxides as those of

Card 1/15

Processes of High-temperature Metal Reduction (Cont.) 306

chromium, calcium, and silicon. Furthermore, such processes are finding more and more application in the ferroalloy and ore-reduction industries. The absence of monographic literature on this question has (until now) hindered the development of these industries. This book deals with the reduction reactions of certain hard-to-reduce oxides, namely those of chromium, manganese, silicon, and phosphorus. The discussion covers equilibrium of the above systems and the molecular kinetics of individual reactions. It is stated that Chufarov, Arkharov, Chizhikov, Vagner, Krupkovskiy, Tumarev and others have contributed to the elucidation of views held by Gryuner, Baykov, Sokolov, and Stark on the mechanism of direct reduction; that Samarin, Khilti, Ol'shanskiy, Khitrik, Richardson, and Tarkdogan have established the nature of intermediate compounds formed in the process of reduction of chromium oxides; that Chufarov, Kapustinskiy, Rode, Simonsen, Vlasov, and Lyuban have contributed much information on the thermodynamic and kinetic aspects of high-temperature reduction of manganese oxides; that much information was obtained from Mikulinskiy, Rapoport,
