<p>The determination of classes of sulfur compounds.  A. S. Bruin and K. M. Zelenyuk. <i>J. Appl. Chem.</i>  (U. S. S. R.) 13, 1407-7 (1910).--The Faragher method  (C. A. 22, 2200) for the analysis of S in motor fuel is not  reliable. A new method is described as follows: First det.  the total S. Then shake an aliquot with 10% NaHCO<sub>3</sub>  and, after removal of the NaHCO<sub>3</sub> layer, analyze for total  S. The difference represents H<sub>2</sub>S sulfur. Take the ali-  quot after removal of H<sub>2</sub>S sulfur and reflux with equal vol.  of 3% Na<sub>2</sub>S at 70° for 10 min. Then analyze the upper  layer for S. The difference in the S content before and  after treatment is elementary S. Det. the mercaptan S  by shaking the sample freed from H<sub>2</sub>S and elementary S  with 5% Cd(OAc)<sub>2</sub>. Det. the mercaptan S by difference.  Then analyze the sample freed from these types of S for  alkylsulfide S by shaking it with powd. HgNO<sub>3</sub>; the dif-  ference in S content is alkylsulfide (R<sub>2</sub>S) sulfur. And  finally, analyze for alkylthiosulfide S(RSSR) by heating the  sample freed from all previously named S compls., with  30-fold excess of 30% Na<sub>2</sub>S in 80% EtOH at 60° for 4 hrs.  The method is recommended for shale gasoline, kerosene  and petroleum products obtained by straight-run distn.  and cracking. A. A. Polgorny</p>

МОРОЗОВ (B. G.), ЗЕЛЕНКА (Mmo L. N.), & КОЗМИНА (Mmo O. A.).  
Влияние болезней на вес и качество семян. [Effect of diseases on  
the weight and quality of seeds].—*Tr. Prikl. Leningr.*, 1936, 10,  
pp. 148-149, 1936.

The authors state that preliminary determinations have shown that  
90 per cent. of tobacco plants infected at an early stage by mosaic fail  
to produce any seed, the yield of the remaining 10 per cent. being less  
than 25 per cent. of the normal; later infections result in a smaller  
reduction of the yield of seed. It was further found that the yield of  
plants suffering from hollow stalk (*Bacillus arvidae*; *R.A.M.*, vii, p. 121;  
xv, p. 346) is reduced by 61 per cent., from powdery mildew (*Erysiphe  
cichoracearum*) by 15 per cent., and from ring spot (*ibid.*, xv, p. 764)  
by 27 per cent. None of these diseases appeared to have any influence  
on the viability of the seed harvested.

TITLE: Swelling and absorption capacity of ion-exchange resins<sup>1</sup> in nonaqueous media

SOURCE: Plasticheskiye massy, no. 2, 1966, 57-59

TOPIC TAGS: nonaqueous solution, ion exchange resin, methanol, acetone, temperature dependence, cation, anion exchange resin, titrimetry

ABSTRACT: The swelling and exchange capacity of ion-exchange resins (the strongly acidic cation-exchange resin SDV-3 in the H-form and the strongly basic anion-exchange resin AV-17 in the Cl-form) were studied in nonaqueous solvents at various temperatures. The temperature dependence of the swelling of the ion-exchange resins in methanol medium was characterized by a convex curve with a maximum corresponding to 16°C; it depended on many factors, including the individual properties of the resin and solvent. The process of swelling was accompanied by diffusion and adsorption of the solvent, which are influenced oppositely by temperature. The swelling behavior was also studied in acetone. The absorption capacity of the ion-exchange resins was determined under dynamic conditions, retaining a constant rate of flow in the column, uniformly filled with the ion-exchange resin. The temperature dependence of the absorption capacities of the cation and anion-exchange resins.

was found to differ; there was also a difference in the dependence of their capacities on the swelling. It was hypothesized that in the case of cation exchange the absorbed solvent in the pores of the swollen ion-exchange resin interferes with the penetration of cations to the active groups, the dynamic exchange capacity therefore increasing with increasing temperature and the swelling decreasing. In the case of anion exchange the molecules of adsorbed solvent promote an increase in the rate of exchange. The exchange capacity of the anion-exchange resin and its swelling reach a maximum at 20°C. The behavior of the cation-exchange resin in nonaqueous media was also studied by potentiometric titration, in which the cation-exchange resin was found to behave as a strong acid, with an exchange capacity of three milligram equivalents per gram. Reactions Between Organo-metallic Compounds and Heavy Metal  
Salts. II. Interaction of Lithium-ethyl With Cobalt and  
Titanium Halides

PERIODICAL:

Izvestiya Akademii nauk SSSR. Otdeleniya khimicheskikh nauk,  
1960, No. 6, pp. 1044 - 1048

TEXT: The reaction of ethyl-lithium with titanium tetrachloride and cobalt chloride is examined here at 20° in hydrocarbon solvents and in the presence of unsaturated hydrocarbons as free-radical acceptors. In the case of radical stages, the said reaction cannot lead to the formation of ethane and ethylene. Similarly, the reaction of organo-magnesium compounds with metal halides was examined earlier (Ref. 12). All reactions were carried out in solutions (in benzene, metaxylol) at 20°. In connection with the fact that α-methylstyrene polymerizes under reaction conditions on the

action of the ethyl-lithium and  $TiCl_4$ , the  $\alpha$ -methylstyrene was gradually introduced to the reaction mixture, thus maintaining a sufficient quantity of free olefin in the mixture at all times. The products of the reaction of ethyl-lithium with cobalt chloride (Table 1) and with  $TiCl_4$  (Table 2) at 20° are given. On the reaction of ethyl-lithium with cobalt chloride, equimolar quantities of ethane and ethylene are liberated, whilst only ethane is liberated when reacting with  $TiCl_4$ , the ethylene being polymerized. The introduction of acceptors in no case affected the composition of the reaction products. The performance of the experiments is exactly described in the experimental part (Fig. 1, reaction vessel with mixer), and hints are given for carrying out the reaction of ethyl-lithium with  $TiCl_4$  and cobalt chloride. The results obtained show that the formation of ethane and ethylene is not connected with radical interstages. There are 1 figure, 2 tables, and 13 references: 4 Soviet, 7 USA, and 2 German.

ABSTRACT:

Sulfur dioxide, by reason of its duality, may be used in redox systems in combination with both oxidizing agents (peroxides, hydroperoxides) and reducing agents (mercaptans,  $H_2S$ , and di-enols). As was shown by the authors (Refs 1,2) these systems may be used to induce radical reactions in hydrocarbon media (Refs 1,2). In the present paper experimental data is given which makes an interpretation of the mechanism of the effect of the above systems possible. The reaction of isopropylbenzene-hydroperoxide with  $SO_2$  is extremely fast in hydrocarbon

solutions and causes a rapid gel formation in rubber solutions. This reaction is accompanied by the formation of polysulfone if styrene is used as a solvent. Nitrogen monoxide prevents this process. Analysis of the reaction products obtained with and without NO proved the reaction to proceed via the radicals ( $\text{SO}_3\text{H}$ ), which react with the monomer to give sulfonic acid. It was shown previously (Ref 2) that the reaction of trichlorothiophenol with  $\text{SO}_2$  produces a vulcanization of rubber at low temperatures. Thus, this reaction leads to the formation of unsaturated polymers. Its mechanism is that of a chain reaction and the reaction proceeds accordingly, and is accompanied by the addition of trichlorothiophenol and  $\text{SO}_2$  to the unsaturated polymer chain. NO prevents this process. There are 3 tables and 7 references, 4 of which are Soviet.

solution of  $\text{NH}_4\text{NO}_3$ , immediately before it begins to evaporate, receives an addition of 0.5% by weight  $\text{Al}_2(\text{SO}_4)_3$  dissolved in the minimum quantity of water; whereupon an excess of a concentrated solution of  $\text{NH}_4\text{OH}$  (with respect to  $\text{Al}_2(\text{SO}_4)_3$ ) is stirred in. After concentrating the solution by evaporation in the process of  $\text{NH}_4\text{NO}_3$  crystallization, 0.25% by weight soap powder is introduced into the mother liquor, after which the  $\text{NH}_4\text{NO}_3$  crystallization is carried to completion. A noncaking product is obtained.

TITLE: The Equivalent Circuit of Damped Longitudinally  
Oscillating Piezoelectric Bars with an Incomplete Electrode

PERIODICAL: Československý Časopis Pro Fysiku, 1959, Nr 1, pp 94-98

ABSTRACT: The arrangement of the electrodes is shown in Fig 4. If  $l$  is the length of the bar,  $l-2c$  is the length of the electrodes,  $a$  is the thickness and  $b$  is the width of the bar,  $m/2$  is the distance between the electrode and the bar. In such a case, we may use the equivalent circuit of Fig 3 (Refs 2, 3) with the values given by Eq (1). The function  $\Phi$  (Eq (2)) for this case is given by Eq (4). By a suitable choice of the relation between the length of the electrodes and the length of the bar, one can exclude certain resonant frequencies. Table 1 gives several examples of this. The measured parameters (Tables 2 and 3) are in good agreement with the theory. There are 4 figures, 3 tables and 5 references, of which 4 are Czech and 1 is English.

TITLE: Experimental Confirmation of Relations Used for  
Designing Longitudinally Oscillating Piezoelectric  
Specimens

PERIODICAL: Československý časopis pro fysiku, 1959, Nr 5,  
pp 463 - 472

ABSTRACT: The electrical properties of a piezoelectric crystal  
oscillating with its  $k$ -th resonance frequency can be  
described by an equivalent circuit consisting of the  
dynamic capacity  $C_R$  in series with the ohmic resistance  
 $R_h$  and the induction  $L_h$ . Parallel to these is the  
static capacity  $C_0$  (see Figure 1). In some cases, it  
is possible to predict the electromechanical behaviour  
of a crystal, i.e. the values of the components of the  
equivalent circuit, from the knowledge of the dielectric  
properties of the bulk material and from the angle of  
cut of the piezoelectric crystal.  
Cady (Ref 5), van Dyke (Refs 9, 10) and Dye (Ref 8) have  
derived equations for computing the equivalent circuit

Card1/4

Experimental Confirmation of Relations Used for Designing  
Longitudinally Oscillating Piezoelectric Specimens

for the fundamental and the odd harmonic oscillations of piezoelectric crystals. Chaloupka, Tichý and Zelenka (Refs 13, 14, 19, 21) have dealt with even harmonics. Cady (Ref 6) has discussed the approximations involved in such derivations. Very few measurements to verify the theoretical relations have, however, been published (Refs 1,2).

The present authors have used three sets of quartz crystals, whose dimensions etc. are described.  $L_h$  and  $C_h$  were

determined by measuring the change in the resonance frequency of the system due to the addition of a known capacity in series with the crystal (Refs 18, 20). The frequency was measured to an accuracy of 0.1 c/sec.  $R_h$

was measured by a substitutional method. The following oscillations were studied: on the first set of crystals the fundamental and the third harmonic longitudinal oscillation. On the second set, the second harmonic longitudinal oscillation, on the third

Card2/4

06626

CZECH/37-59-5-2/13

Experimental Confirmation of Relations Used for Designing Longitudinally Oscillating Piezoelectric Specimens

(unsilvered) set, only the fundamental longitudinal oscillation.

Except for the third harmonic, all resonance frequencies were in good agreement with the well-known equation (1). The lack of agreement with this equation of the third harmonic is probably due to coupling with other modes and to the finite thickness of the crystals.

For the theoretical calculation of  $L_h$  and  $C_h$  we have used equations (3) and (4) (Ref 14).

Figure 3 shows the dependence of  $L_h$  on the angle of cut of the crystal both for silvered and unsilvered samples. The frequencies were the fundamental frequency and the third harmonic. Figure 4 shows the same dependence for the second harmonic on a silvered sample. Agreement between theory and experiment is good for the fundamental and second harmonic, but not for the third harmonic oscillation.

06626

CZECH/57-59-5-2/13

**Experimental Confirmation of Relations Used for Designing Longitudinally Oscillating Piezoelectric Specimens**

The agreement between theory and experiment enables one to determine the piezoelectric coefficients from the equivalent circuit. The main advantage of the confirmed agreement is the possibility of designing crystal filters with well predictable characteristics.

There are 6 figures, 2 tables and 31 references, of which 7 are Czech, 9 English, 4 German and 1 Soviet.

TITLE: Synthetic Piezoelectric Materials <sup>11</sup>

PERIODICAL: Slaboproudý obzor, 1960, Vol 21, No 2, pp 66-72

ABSTRACT: A number of synthetic piezoelectrics have been developed since World War 2. The manufacture and the properties of most of these materials are reviewed in the article. Two tartrates EDT and DKT are employed as piezoelectric materials. The first tartrate has the following formula:  $C_6H_{14}N_2O_6$ ; the formula for DKT is  $K_2C_4H_4O_6 \cdot \frac{1}{2} H_2O$ . The monocystals of these substances crystallize in the sphenoidic system. The crystals are illustrated in Fig 1. In both cases the Z axis is identical with the crystallographic axis c and the Y axis is identical with b crystallographic axis. The angle between X axis and the crystallographic a axis is  $15^\circ 30'$  for EDT crystals and only  $51'$  for DKT crystals. Optically both crystals are bi-axial. Various physical and electrical parameters Card 1/3 of these crystals are indicated in Table 1. The crystals

Z/039/60/021/02/002/037  
E192/E535

# Synthetic Piezoelectric Materials

can be used in resonant circuits and give a quality factor up to 30 000. Lithium sulphate LSH having the formula  $\text{Li}_2\text{SO}_4 \cdot \text{H}_2\text{O}$  is also a useful piezoelectric material. The crystal of LSH has the form shown in Fig 3. The physical and the electrical constants of this material are indicated in Table 2. Sorbitol hexa-acetate, SHA having the formula  $\text{C}_6\text{H}_8\text{O}_6(\text{COCH}_3)_6$  gives crystals which are soluble in water. The shape of the crystal is illustrated in Fig 4 and its piezoelectric coefficients are indicated in Table 3. This material can also be used in resonant circuits. Phosphates ADP and KDP can be used in electro-acoustics where Rochelle salt has been normally employed; the chemical formula of ADP is  $\text{NH}_4\text{H}_2\text{PO}_4$  while that of KDP is  $\text{KH}_2\text{PO}_4$ . Both materials crystallize in a tetragonal system (Figs 5 and 6). The basic properties of these materials are indicated in Table 4. The crystals of ADP and KDP do not contain any

TITLE: Longitudinal and Contour Shear Vibrating Piezoelectric  
Resonators from Synthetic Quartz <sup>6</sup>

PERIODICAL: Československý časopis pro fysiku, 1960, No 4,  
pp 328-332

ABSTRACT: To verify their properties, measurements were made on  
longitudinally vibrating narrow XYt<sub>-φ</sub>-cut rods (for  
φ = 0° to 5°) and square-shaped DT-cut plates (YXl<sub>52°30'</sub>)  
Two sets of resonators were produced, one was made of  
natural and the other of synthetic quartz single crystals.  
All the synthetic quartz specimens were produced from a  
single monocrystal weighing 0.8 kg and grown from a  
germination in the form of a plate, with the thickness  
in the direction of the Z-axis, at a temperature of  
300-350°C and a pressure of about 400 atm. Data of the  
resonators are given. The oscillations were generated  
by means of a Heegner oscillator for which it could be ✓

assumed that it excited series resonance in the quartz crystal. Care was taken that in generating the oscillations the voltage of the resonator should be as low as possible and that it should have a purely sinusoidal characteristic. In measuring the temperature dependence the resonators were sealed into evacuated glass ampoules, which were placed into an airstream which could be heated or cooled as required; the measurements were carried out with an accuracy of  $\pm 0.5^{\circ}\text{C}$  for at least 20 mins. The results of the measurements are described and discussed. The results proved that the piezoelectric and the elastic properties of synthetic single quartz crystals grown from germinations of the Z cut are fully satisfactory and such crystals are suitable for generating longitudinal and "contour shear" vibrating piezoelectric resonators. The slight differences in the location of the peaks of the parabola of the temperature dependence of the frequencies of narrow

longitudinally vibrating rods can be excluded by appropriate selection of the orientation of the cut used. For achieving an equal temperature dependence of the frequency of longitudinally vibrating rods of the cut  $XYt_{-\varphi}$ , it is necessary to apply in resonators with synthetic quartz crystals an angle  $\varphi$  smaller by about  $1^\circ$ . The dynamic inductance and the  $Q$  of resonators made of natural and synthetic quartz crystals are approximately equal. For contour shear vibrating DT-cut crystals made of synthetic quartz, the inductance is about 4% smaller and the  $Q$  is about one-third lower than it is for resonators with natural quartz crystals. Similarly, the temperature dependence curve is shifted and the zero temperature dependence of the frequency is achieved at temperatures approximately  $7^\circ\text{C}$  lower than for natural quartz crystals. There are 2 figures, 3 tables and 15 references, 2 of which are Czech, 4 Soviet, 2 German, 1 Swiss, 1 Polish and 5 English.

AUTHOR: Zelenka, Jiří, Engineer

TITLE: Piezoelectric Resonators for Very Low Frequencies

PERIODICAL: Slaboproudý obzor, 1961, Vol. 22, No. 2,  
pp. 66-70

TEXT: For the frequency band from 1 to 3 kc/s piezoelectric resonators are in the form of two crystal slabs attached to each other in such a way that the voltage applied to the electrodes results in the elongation of one of the slabs and the contraction of the other. For the resonators operating above 3 kc/s, the slabs are almost square in cross-section and the electrodes are attached to either 4 or 6 walls of the crystal. The frequencies above 8 kc/s are covered by the resonators, which are in the form of thin slabs. In this case, the flexural oscillations are produced by means of 4 electrodes situated on 2 parallel surfaces of the crystal. In general, the frequency range between 1 and 10 kc/s is based on the resonators which operate in the flexural oscillation mode. A resonator of this type can operate at its h-th  
Card 1/5

Piezoelectric Resonators ....

Z/039/61/022/002/001/003

E192/E382

resonant frequency and it can be represented by an equivalent electrical circuit, having the form of a bipole, a tripole or a quadripole. In determining such a circuit it is necessary to know 4 parameters, namely, the series resonant frequency  $f_h$ , dynamic inductance  $L_h$ , ratio of the static and dynamic capacitances  $C_o/C_h$  and the equivalent series resistance  $R_h$  or the quality factor  $Q_h$ . The resonant frequency of flexural oscillations of rods or narrow slabs can be expressed by (Ref. 5):

$$f_h = \frac{m_h^2}{4\pi\sqrt{3}l} p \frac{1}{\sqrt{s'_{ii}\rho}} \quad (3)$$

where  $s'_{ii}$  is the modulus of elasticity of the crystal in the direction of its length  $l$ ,  $p$  is the ratio of the

Card 2/5

89310

Z/039/61/022/002/001/008

Piezoelectric Resonators ....

E192/E382

crystal thickness  $t$  to its length (if the flexural oscillations occur in the direction of the thickness) or the ratio of the width  $b$  to the length if the slab oscillates in the direction of the width;  $\rho$  is the density of the crystal and  $h$  denotes the order of the oscillation. The magnitude of the coefficient  $m_h$ , which is dependent on the ratio  $p$ , was theoretically derived by Mason (Ref. 4). The values of this coefficient taken from Mason's work were used to calculate the resonant frequency as a function of  $b/\ell$  and the results are given in a figure together with corresponding experimental curves. Reasonably good agreement between theory and experiment can be observed. The inductance and the capacitance of the equivalent electrical circuit of a resonator operating in the vicinity of its principal flexural resonance can be evaluated from the formulae derived by Keller (Ref. 3). The quality factor  $Q$  of the resonators is dependent on the density of the medium in which the resonator oscillates. The effect of air pressure on  $Q$  was investigated experimentally and it is shown that it is desirable to keep the resonators

Card 3/5

89310

Piezoelectric Resonators ....

Z/039/61/022/002/001/008  
E192/E382

in vacuum in order to achieve a high  $Q$ . The temperature-frequency dependence of the resonators was also investigated and it was found that a parabolic dependence of frequency on temperature could be achieved for all the types of resonator. The flexurally operating resonators for the frequencies from 1 to 10 kc/s are normally used as stable frequency sources. In general, the resonators are connected as bipoles or, more often, tripoles. A typical oscillator circuit with a resonator connected as a tripole is shown in Fig. 7. In this the piezoelectric element, which is connected between the anode and grid circuits of the tube, represents a narrow-band filter whose bandwidth can be adjusted by means of the variable capacitance  $C_g$ . In the extreme case, it is possible to obtain the bandwidth almost equal to the "distance" between the series and parallel resonances of the resonator. At the centre frequency of the filter the phase shift between the terminals 1-3 and 2-3 is  $180^\circ$  so that the condition necessary for the oscillation is achieved. The flexurally oscillating

resonators are very useful at frequencies between 1 and 10 kc/s but their Q and long-term frequency stability are poorer than those of longitudinally or shear-type oscillating crystals. There are 9 figures, 2 tables and 11 references: 5 Czech and 6 non-Czech.

TITLE: Influence of radiation on the properties of piezoelectric resonators

PERIODICAL: Československý časopis pro fysiku, no.2, 1962, 144-151

TEXT: The effect of radiation on piezoelectric oscillators is one of the environmental influences which are becoming important as demands on the accuracy and stability of crystal oscillators increase. The authors briefly review the field of radiation damage in solids in general and in piezoelectric crystals in particular, before describing their own experiments on oscillators from natural quartz and from DKT. The source of radiation was either Co-60 or X-rays from a copper target at 35 kV. No change was detected in the longitudinal vibrations of quartz oscillators cut in the XYa<sub>50</sub> direction due to irradiation by several hundred r units of X-rays and up to 10<sup>5</sup> r units of γ rays. This result is in agreement with published

Card 1/3

Influence of radiation on the ...

Z/037/62/000/002/007/015  
E024/E135

results. On the other hand, the torsional vibrations of type BT quartz-crystal-oscillators with orientation  $YX\ell_{40}20'$  at about 13 Mc/s were influenced by irradiation. Irradiation by up to  $10^5 \times 10^3$  r of X-rays gradually reduced the resonance frequency from over 13514 kc to under 13510 kc. The reduction in the resonance frequency tended to saturate. A similar oscillator with a resonance frequency of 10 Mc/sec was irradiated by up to  $10^5$  r of  $\gamma$ -rays. This irradiation reduced the resonance frequency only very slightly and barely influenced the temperature-dependence of the frequency. Similar results were obtained with oscillators of the type AT with orientation  $YX\ell_{-350}10'$ . The influence of X-rays on oscillators made from DKT was studied on samples cut in the  $XZa_{370}30'$  orientation at about 100 kc/sec. Irradiation with about  $3 \times 10^3$  r reduced the resonance frequency by 4-5 cycles if the crystal was sealed in a glass envelope and by about 12 cycles when irradiated in the open. No change in the temperature-dependence of the frequency was detected. It appeared that irradiation

Card 2/3

Influence of radiation on the ... Z/037/62/000/002/007/015  
E024/E135

was more effective if carried out while the crystal was vibrating. The theoretical interpretation of the above results has not yet been clarified.  
There are 3 figures.

TITLE: The Q-factor of contour modes of vibration of piezoelectric resonators

PERIODICAL: Československý časopis pro fysiku, no.2, 1962, 182-185

TEXT: The use of piezoelectric resonators in high-precision oscillators often requires a high Q-factor and high stability of the resonance frequency of the resonator. The author considers frequencies between 60 and 150 kc/sec. The Q-factor of rod-shaped quartz resonators of orientation XYt<sub>50</sub> and thickness above 0.8 mm is usually about 130 000. The Q-factor can be increased by optically polishing the surfaces. With a resonator of dimensions 50 x 5 x 1.2 mm, at 22 °C, a Q-factor of up to 220 000 has been achieved. Quartz resonators of type DT, vibrating in contour shear modes, a Q-factor of 220 000 can be achieved even with ground faces. The highest values of Q are, however, attainable with GT-type resonators. An optically polished resonator of this type, with thickness 1.2 mm and

resonance frequency 100 kc/sec, can have a Q value up to  $1.6 \times 10^6$  at 22 °C. The Q-factors for resonators cut from DKT are altogether lower. The Q-factor is usually rather dependent upon temperature. However, this dependence can be decreased by suitable methods of mounting. The high Q-values themselves can only be achieved if the crystals are correctly mounted. There are 2 figures.

TITLE: Contribution to the equivalent circuit of piezo-electric resonators, taking into consideration the influence of secondary resonances

PERIODICAL: Československý časopis pro fysiku, no.2, 1962, 186-187

TEXT: A possible method of simplifying the equivalent circuit of a piezo-electric resonator in a certain, arbitrarily chosen, frequency range is presented. The equivalent circuit is considered in the form of a two-pole network consisting of a finite number of series resonance circuits, a frequency-dependent capacity and a frequency-dependent resistor connected in parallel. The individual series resonance circuits, the resonance frequencies of which are outside the frequency range under consideration, are substituted in the simplified equivalent circuit by an admittance, the real part of which can be considered as expressing the conductivity of the frequency-dependent resistance, whilst the imaginary part can be considered as the frequency-dependent capacitance. The high quality factor of the

piezo-electric resonator allows disregarding the real component of the admittance and taking into consideration the influence of distant resonances by means of the frequency-dependent capacitance. Depending on the position of the resonance, this capacitance will be positive or negative and will increase or lower the static capacitance of the resonator. The possibility of applying the here given interpretation of the natural resonances of the piezo-electric resonators in an equivalent circuit was experimentally verified for type GT quartz resonators.

TITLE: On the electrical equivalent circuit of a piezoelectric resonator

PERIODICAL: Elektrotechnický časopis, no.3, 1962, 142-154

TEXT: The author derives a simplified equivalent circuit valid in the neighbourhood of a resonance of a piezoelectric crystal, differing from the usual circuit in that the parallel capacitance is not the low-frequency shunting capacitance of the electrodes but a function of frequency, which may take on both positive and negative values. Formulae are given which follow measured curves very closely, employing a few parameters measured at fixed frequencies. There are 9 figures, 3 tables and 13 references: 8 Soviet-bloc and 5 non-Soviet-bloc. The four references to English language publications read as follows: Ref.2: Cady W.C., Piezoelectricity. TITLE: Determining the attenuation decrease of narrow-band quartz filters in the neighborhood of undesirable responses of resonators

PERIODICAL: Slaboproudý obzor, v. 23, no. 4, 1962, 201-207

TEXT: The article deals with an investigation on the influence of undesirable responses of piezoelectric crystals on the attenuation response of narrow-band quartz filters made up of crystal vibrators and capacitors. The author states that the influence of undesirable responses upon filter transfer characteristics constitute a serious problem in the design of filters with mechanical resonators. These resonances cause an attenuation decrease in the suppressed frequency range and an attenuation increase in the band-pass range. This problem is especially serious in the utilization of piezoelectric resonators, ground out of monocrystals with low symmetry, whose high degree of disturbing resonances was pointed out by

E.G. Bronnikova (Ref. 1: O parazitnykh kolebaniyakh pezoelektricheskikh plastin s osnovnymi prodolnymi kolebaniyami. Izvestiya AS USSR, seriya fiz. XX (1956), p 251). The attenuation decrease within the suppressed frequency range is characterized by a limit value, below which the attenuation of the filter will not decrease under influence of undesirable response, in the piezoelectric vibrators and within a specified frequency range. The validity of this limit value was confirmed in experiments and calculated by a method described in a paper by J. Zelenka (Ref. 9: Slabe proudy obzor, no. 18 (1957), p 696); (Ref. 11: Elektrotechnicki casopis XIII (1962)). The limit value of attenuation can be determined from the parameters of the electrical equivalent circuit of the crystal vibrators and the values of the respective filter networks, thus permitting the creation of conditions which make the influence of undesirable resonances of piezoelectric resonators tolerable from a standpoint of attenuation characteristics. There are 11 figures; 4 tables and 11 references: 8 Soviet-bloc and 3 non-Soviet-bloc. The references to the English-language publications read as follows: W.G. Cady: Piezoelectricity. The relationship between the resonance frequency of GT-cut crystals and time is depicted in Figure 2 of Enclosure 4. The interpolated log curve is given by Equation 2 of Enclosure 2.

The relative daily stability of the resonance frequency of GT crystals was measured on specially prepared quartz crystals placed in a vacuum in a desiccator. The relative stability was measured after 1 day, 10 days, and 100 days respectively. It was concluded that shape essentially affects the long-term stability.

The quality factor  $Q_s$  of GT crystals was measured in relation to temperature. For GT crystals with a resonance frequency of 100 kc/sec, it was found that  $Q_s$  is  $2.5 \times 10^5$ . The results of this study are given in Figure 3 of Enclosure 4. The quality factor of a plano-convex AT crystal with a 30 mm-diameter and 3.284 mm-depth, and of another which was 22 mm in diameter and 1.192 mm deep, was measured in terms of their resonance frequencies when the radius of the curvature of the domes was 100 mm. The results are presented in Figure 7 of Enclosure 6.

The article is supplemented by photographs of the resonators
