

A Closed Convective Boundary Layer

SOV/20-124-2-15/71

The authors do not give the entire calculations but only the final formulas: $\omega = 0.629 (\nu/R^2)(G/\text{Pr})^{1/2}$;
 $\delta = 4.34 R(G/\text{Pr})^{-1/4}$; $\alpha = -2.69$; $\beta = -(4.03 + 1.55/\text{Pr})$.
By means of the formulas derived it is possible to calculate the density of the heat flow on any point of the surface.
Finally, a formula is given for the total heat current passing through the cross section. The condition for the existence of the investigated convective motion is $G\text{Pr} > 350$. At low values of the Rayleigh (Roley)- parameter $G\text{Pr}$ there is a weak convection without the formation of a boundary layer. There are 1 figure and 4 references, 1 of which is Soviet.

Phosphate Fertilizers

"Review of Professor N. S. Avdonin's Pamphlet,
"A New Effective Method of Using Mineral Ferti-
lizers," A. Zhukov, I.P.

"Nauka i Zhizn" No 9

When superphosphate is used haphazardly, only a small part can be utilized by the plant. Avdonin suggested that superphosphate be used in granulated form and introduced into soil in small doses. At T. D. Lysenko's suggestion, Soviet chemical industry has begun production of

150T1

USSR/Agriculture - Fertilizers, Mineral Sep 49

stream was directed to the point
blown over the point without
blow.

Card 2/3

L 16873-5)
ACCESSION NR: AR3006301

increased current of positive ions to the indicated collector was observed only before the very first discharge. When the source of the negative ions was turned off, the current of positive ions to the collector increased sharply. A noticeable growth in the current is observed even at voltages that are 40--50 per cent lower than the voltage of the first discharge. The power of the discharge is proportional to the square of the voltage.

Upon turning on the source of negative ions, the current of positive ions to the collector decreased sharply.

The current of positive ions to the collector decreased sharply with increasing voltage, and at a certain voltage, the current became zero.

The current of positive ions to the collector decreased sharply near the positive breakdown voltage.

AUTHOR: Gulyayev, B.B.
 SOV/24-58-4-37/59

TYPE: Conference on Crystallization of Metals (Soveshchaniye po Kristallizatsii Metallov)

PUBLISHER: Izdatelstvo Akademii Nauk SSSR. Otdelenie Tekhnicheskikh Nauk, 1958, Nr. 4, pp. 153 - 155 (USSR).

ABSTRACT: This conference was held at the Institute of Mechanical Engineering of the Ac. Sc. USSR (Institute of Mechanical Engineering of the Ac. Sc. USSR) on June 25-27, 1958. About 200 people participated and the participants included specialists in the field of foundry metallurgy, crystallography, physics, welding, heat treatment, mechanical physics, mathematics, related subjects. In addition to Soviet participants, foreign scientists included Professor D. Cahn (West Germany) and M.T. Chvorinov (Czechoslovakia). This conference on crystallization of metals was the fourth conference relating to the scientific problems of the theory of foundry processes.

Conference on Crystallization of Metals
 Sov/24-58-4-37/59

Crystallization of Cast Iron. I.A. Shaburov and
 Yu. P. Kupriyanov. In their paper "Investigation of the Process of Crystallization of Magnesium-Inoculated Iron", reported on separate and due relation to the conditions of solidification and the structure of castings made of magnesium-inoculated iron, they presented a theory of crystallization of magnesium-inoculated iron.

J. A. Balli. In his paper "Investigation of the Process of Formation of Spheroidal Graphite in Iron", considered the influence of various factors and characteristics of the metal on the formation of graphite inclusions. Professor D. Cahn (West Germany) presented a paper on crystallization of graphite in cast iron, which was illustrated by extensive metallographic photographs.

Z.N. Malinovskaya and A. N. Chikishev. In their paper "On the Structure of Cast Iron", dealt with the problem on the structural differences between cast iron and its influence on the properties of cast iron.

I.I. Doroshev and V.V. Lai. In their paper "Investigation of the Mechanism of Crystallization of Graphite in Castings Made of White Iron and the Influence of Alloying Elements Between the Individual Phases of Iron-Carbon Alloys". I.V. Balli proposed a method of increasing the speed of cooling the liquid state using an extremely high bath enabled conservation of saturated solutions of carbon in iron which correspond to the liquid state.

N.Ya. Kshepovetsky. In his paper "Investigation of Crystallization, the Primary Structure and the Properties of Quasi-eutectic Fe-7% Mn",

TITLE: Minimum voltage protective circuits with time delay
operated by a.c. (Skhemy zashchity minimal'nogo
napryazheniya s vyderzhkoy vremeni na peremennom
operativnom toke)

PERIODICAL: Promyshlennaya Energetika, 1958, Nr 8, pp 21-24 (USSR)

ABSTRACT: When operating circuits are converted from d.c. supply
with storage batteries to a.c. supply it is minimum voltage
protection that gives rise to the greatest difficulties.
Several circuits have been developed for this purpose and
are briefly described but none of them is quite
satisfactory. The Gor'kiy Division of the State Planning
Institute Elektroprojekt has developed new minimum
voltage protective circuits which are much better than
previous ones. The special feature of these circuits is
the use of one relay type EN-500 connected to two (Fig.1)
or three (Fig.2) line voltages through selenium or other
rectifiers. A capacitance is connected in parallel with
the relay winding so that if one of the transformer fuses
blow the voltage on the relay is almost unaltered. If the
circuit of Fig.1 is used the voltage on the relay is
halved but this difficulty is overcome by the circuit of

Card 1/3

SOV/94-58-8-9/22

Minimum voltage protective circuits with time delay operated by
a.c.

Fig.2. The advantage of these circuits is that the relay EN-500 works entirely without vibration. The way in which the circuit of Fig.2 may be used to supply the operating circuit of a circuit breaker is shown in Fig.3. Figs. 4, 5 and 6 show different methods of obtaining time delay. Fig. 4 shows a circuit employing relay type EV-100 which operates when voltage is removed from the winding. The circuit of Fig.5 uses time-delay type MKU-48 which can give time delays of up to 10 seconds. Fig.6 is based on other relays which can give time delays of up to 15 seconds. The circuits in Figs.7, 8 and 9 show different methods of group minimum voltage protection using the elements already described. The results of tests made with some of these relays are given. It is concluded that minimum voltage protection can easily be arranged for a.c. operating current. Circuits that use very little power for minimum voltage protection with time delay can be obtained by using relay type MKU-48

The Causes of Reverse Chilling of Cast Iron (O prichinakh
obratnogo otbela chuguna)

PERIODICAL:

Liteynoye proizvodstvo, 1958, Nr 12, pp 29 - 30 (USSR)

ABSTRACT:

In a letter to the editor, the author rejects the theory stated by Neizhko in the previous article, assuming a cause of reverse chilling of cast iron to be the reduced number of graphitization centers in the peripheral portions of metal castings. He states that reverse chilling of cast iron is mainly caused by the difference in degree of its residual intercrystalline segregation in different zones of the casting, and can be observed in particular, in zones of developed silicon segregation, which is intensified by the large-grain metal structure in the center of the casting. There are 2 photos and 2 graphs.

AUTHOR: Zhukov, A.A. (Engineer)
TITLE: On the Brittleness of High Strength Spheroidal Iron
(O khrupkosti vysokoprochnogo chuguna s sharovidnym
grafitonom)
PERIODICAL: Metallovedeniye i Termicheskaya Obrabotka Metallov,
1959, Nr 4, pp 53-55 (USSR)
ABSTRACT: Kudryavtsev et alii (Ref 1) found that an increase in the
impact strength of high strength cast iron with
increasing temperature is due to position of the
brittleness threshold of such iron. Thus, the temperature
of the brittleness threshold of pearlitic irons is very
high, amounting to 200°C. The author of this paper
considered it of interest to study the possibility of
reducing the temperature of transition of this material
into the brittle state. Results of G.N. Gilbert (Ref 2)
show that the constituents of the high strength cast
iron are particularly harmful as can be seen from the
graph (Fig 1) in which the influence is plotted of the
Si and P contents on the location of the brittleness
threshold of high strength spheroidal irons. Phosphorus
increases appreciably the brittleness threshold only if
its content exceeds 0.08 to 0.1%. The base structure of
Card 1/3

SOV/129-59-4-12/17

On the Brittleness of High Strength Spheroidal Iron
the metal also has a considerable influence; the lowest brittleness threshold temperature (-50°C) was observed for ferritic high strength cast irons (Ref 2). The brittleness threshold is greatly influenced by the stress concentrations; it can be seen from the data of Tables 1 and 2 that, as a result of notching, a tough iron may become brittle. The brittleness threshold temperature can also be reduced by heat treatment. Fractures in components made of high strength iron, without traces of residual plastic deformation and without any signs of fatigue breaks, which do occur in practice, are attributed to the fact that the metal is in the brittle state at the respective operating temperature. On the basis of the obtained data a number of recommendations are made, one of which is that, in view of the fact that stress concentrations bring about a displacement of the brittleness threshold in spheroidal irons, impact strength

TITLE:

Construction of the Dnepr - Krivoy Rog Canal

PERIODICAL:

Gidrotekhnika i melioratsiya, 1959, Nr 11, pp 24-33
(USSR)

ABSTRACT:

This article describes the Dnepr - Krivoy Rog Canal, presently under construction, as well as some of the methods and equipment used in its construction. The canal - 42.2 km long - has its source in the Kakhovskoye vodokhranilishche (Kakhovka reservoir), passes thence to the west of the town of Apostolovo and ends in the Yuzhnoye reservoir (capacity - 36.5 million cubic meters), located in the Taranovoy and Chebanke gorges. From here water will be carried by open canals to the Kresov reservoir on the Saksagan' river, and to the Ingulets river, and by closed pipe-line to a filter station and the industrial enterprises of Krivoy Rog. The overall reserve capacity of the Yuzhnoye and Kresov reservoirs is 51 million m³. Construction of the canal, state the authors, is aimed at

Card 1/6

SOV/99-59-11-6/15

Construction of the Dnepr - Krivoy Rog Canal

solving the problem of water supply to the Krivoy Rog basin, and the canal should deliver more than 650 million m³ of water yearly to consumers, of which 500 m³ is intended for technical needs, 100 million m³ for household and drinking use and 50 million m³ for irrigation purposes; the overall land area to be irrigated by the canal will be 24,500 hectares, with the prospect of raising this figure to 41,500 hectares. Dimensions of the canal are given, and a cross section diagram presented (Fig 3); it is computed that the canal will handle 38 m³/sec of water; the upper part of the banks is reinforced with a 0.2 meter layer of pulverized rock. The canal route is mapped (Fig 1) and briefly described. Raising water from the level of the Kakhovka reservoir to that of the Yuzhnoye reservoir (a difference of 85 m) will be accomplished by three pumping stations equipped as follows: installed in the first station will be 56 V-17 vertical cantilever centrifugal pumps with a metallic spiral chamber, in the second and third stations, OP 4-145 vertical rotary axial pumps; each pump is directly connected with

Card 2/6

SOV/99-59-11-6/15

Construction of the Dnepr - Krivoy Rog Canal

a synchronous electric motor, and the power of the electric motors varies from 700 to 2000 kw; the start-stop process at all stations is fully automatized, and may be controlled locally as well as from a control point. Other constructions along the canal route are outlined, including 59 km of road, 50 km of 35 kv transmission line, 42 km of 6 kv transmission line and 35/6 kv electric sub-stations; as of the middle of 1959 35 km of 35 kv line, 42 km of 6 kv line and three of the sub-stations were built, and 7 km of the canal were completed. Work on the canal was started in the second half of 1957 by the ordena Lenina spetsializirovannoye stroitel'no-montazhnoye upravleniye "Dneprostroy" (Specialized Construction-Installation Administration of the Order of Lenin "Dneprostroy"); construction offices are located in Apostolovo and Mar'yanskaya. Among other facilities listed is a concrete works in the village of Radushnoye (Fig 4). Work on the canal and road beds is to be done by the Upravleniye mekhanizirovannykh rabot "Dneprostroya" (Office of Mechanized Works of "Dneprostroy").

Card 3/6

SOV/99-59-11-6/15

Construction of the Dnepr - Krivoy Rog Canal

The following equipment is presently in use: 25 excavators, 50 bulldozers, 12 scrapers, 7 graders, 4 motor-graders, 1 grader-elevator, 21 tractors and 10 rollers. Earth work was begun in February, 1958, and full mechanization of this work is projected; excavators are to handle 70%, scrapers - 20% and bulldozers - 10% of the overall volume of this work. Various methods of working on the canal bed are outlined. One method, very briefly described, proposed by the Nauchno-issledovatel'skiy institut organizatsii, mehanizatsii i ekonomiki stroitel'stva i arkhi-tektury USSR (Scientific-Research Institute of the Organization, Mechanization and Economics of Construction of the Academy of Construction and Architecture of the UkrSSR) in 1958 is illustrated (Fig 5) using a bulldozer on an S-80 tractor. Use of a D-20A grader on the canal banks is also shown (Fig 6). Construction work on the earth dike of the Yuzhnoye reservoir is also briefly described and illustrated (Fig 7). The authors report that first use of the ZFM-3000 excavating-cutting machine, an experimental model of which

Card 4/6

SOV/99-59-11-6/15

Construction of the Dnepr - Krivoy Rog Canal

was produced by the Voronezhskiy gosudarstvennyy ekskavatornyy zavod imeni Kominterna (Voronezh State Excavator Works imeni Komintern), was made in the construction of the Dnepr - Krivoy Rog canal; this excavator is self-powered by a diesel-electric power installation and equipped with hydraulic control, and is intended for digging canals up to 40 m across (at the top) and up to 6m deep; some specifications are given and its operation and use are described and illustrated (Fig 9). At present the excavator is undergoing tests. Also in use at the canal are bulldozers on DET-250 and S-100 tractor units; the DET-250, put out by the Chelyabinskij traktornyy zavod (Chelyabinsk Tractor Works), with 250 hp has a diesel electric motor (300 V) and DK-913 auxiliary electric motor; the DET-250 is illustrated (Fig 10); the DET-100 is a 100 hp unit; some specifications for both units are given; both are equipped with hydraulic control systems, and both are under tests at the canal site. Briefly discussed is a study of improvement in the organization of excavating and facing work in canal construction

Card 5/6

SOV/99-59-11-6/15

Construction of the Dnepr - Krivoy Rog Canal

started in 1958 by the Scientific-Research Institute of the Organization, Mechanization and Economics of Construction of the Academy of Construction and Architecture of the UkrSSR in connection with construction of the Dnepr-Krivoy Rog Canal. In conclusion the authors note that the canal is expected to be finished in 1960. The following persons are mentioned: V. Pavlov, bulldozer operator, I. Dashko, V. Filenko, I. Guba and M. Simorod, scraper operators, G. Il'kiv and M. Dudarev, tractor drivers, and V. Shevtsov and A. Primak, excavator operators. There are 7 photographs, 1 map and 2 diagrams.

TEXT: Data on the principles of drawing diagrams for the alloys Fe-C-Si, Fe-C-P, and Fe-C-Si-P using combined sections are given in this paper. When the polythermal section technique is used for the diagram of the ternary system Fe-C-Si along the tie lines solid solution - eutectic alloy - cementite (or graphite, respectively), diagrams are obtained which show no fundamental difference from those for binary alloys. From the conoidal section, the phase composition can be quantitatively determined, as well as the composition of the eutectic alloy during the initial period of eutectic conversion, and, finally, the degree of eutecticity using the lever rule. To determine the change in composition for the alloy during eutectic conversion, the oblique polythermal section of the ternary diagram according to the thalweg $CL_{1k}L_{2k}K$ (Fig.5) was used. When this section was projected

onto the plane of the Si-C diagram, it was shown that it is actually the classical binary eutectic system consisting of carbon (γ -y β , i.e., carbon eutectic of γ -iron) and silicon (α -K β , i.e., silicon eutectic of α -iron - FeSi) having two peritectic faces. The sum of components on the diagram scales in Fig. 3 is not 100%, contrary to the diagrams for binary alloys; the iron content is established from this difference. Fig. 4 shows the projection of the oblique polythermal section of the phase diagram Fe-C-P according to the thalwegs adjacent to the 100%-Fe corner. In this case, a eutectic system consisting of a carbon (γ -y β) and a phosphide (α -P β , i.e., the phosphide eutectic of α -iron) eutectic, having one eutectic and one peritectic face, is involved. When the crystallization of ternary alloys undergoing eutectic conversion is studied, two two-dimensional diagrams, i.e., combined conodial and thalweg sections of the ternary diagram, can be used instead of the three-dimensional one, with the conodial section representing the state of the alloy prior to eutectic conversion and the thalweg section representing it during this process. The technique described can be used to plot ternary diagrams for quaternary eutectic alloys, where the oblique section of the concentration tetrahedron has to be accomplished along the faces of the eutectic alloys adjacent to the 100%-Fe

corner, and the section obtained has to be projected onto a plane. In contrast to Kurnakov's singular polyhedration, this method is called "eutectic polyhedration"; it reduces the dimension of the diagrams obtained by one order of magnitude with respect to the initial diagrams. There are 6 figures and 6 Soviet references.

TITLE:

PERIODICAL: Fizika metallov i metallovedeniye, v.13, no.2, 1962,
280-287

TEXT: The author discusses the relations between the positions of lines in alloy phase diagrams and thermodynamic-activity diagrams of the alloy components of the alloy. Several examples are given of the wide scope of the method for obtaining greater precision of the position of phase boundaries, particularly for iron-carbon alloys and Fe-C alloys with silicon or phosphorus. The solidus line for austenite in the Fe-C diagram is discussed. Using the iso-activity lines for the areas on either side of this line, the author shows lines that contradict those in the literature. This is convex with respect to the austenite + liquid region. This agrees with one view (Ref.3) but contradicts another (Ref.10). The author applies similar methods to sections of ternary systems.

Phase diagrams and thermodynamic- ...

In the 1155 °C isothermal section of Fe-C-Si there are contradictory views on the position of the conode austenite-eutectic melt (Fig. 2: line 1 gives the position according to one group of workers (Refs. 10-12); line 2 that according to J.E. Hilliard, W.S. Owen (J. Iron and Steel Inst., v. 172, no. 3, 1952)). The author shows the former to be correct, indicating that, in accordance with experience, a higher silicon content in eutectic Fe-C-Si melts promotes graphitization of the alloy. Application of the method to the Fe-C-P system explains various features of the phase diagram and microstructure. It shows why in low- or medium-silicon irons cementite and not graphite is the high-carbon phase, and contradicts the view of F. Neumann et al. (Ref. 3) that phosphorus in grey iron is a graphitizing addition. The author notes that thermodynamic activity is convenient not only for determining the tendency of iron-carbon alloys to graphitization, but also for estimating other properties such as creep. His approach will provide a convenient bridge between thermodynamic and kinetic factors, metal physics and classical metallurgy. There are 7 figures.

TITLE: Developing and studying an installation for hydraulically removing scale from heated blanks

PERIODICAL: Kuznechno-shtampovochnoye proizvodstvo, no. 1, 1963, 21 - 24

TEXT: The authors point out that, to improve the surface finish of die-forged parts, the hydraulic method of removing scale from the heated blanks is the most advanced one, and is used, apart from plants in the USA, England, Poland and other countries, also by machine-building and metallurgical plants of the Soviet Union, e.g. "Zaporozhstal'", "Krasnyy Oktyabr'", "Serp i molot" and other plants. This method consists in pointing a thin high-pressure water jet of some 100 - 180 atm at the blank heated up to forging temperature. Under the effect of the kinetic energy of the water and, simultaneously, of local cooling, the scale bursts and can be removed from the surface without the blank itself being cooled down. The two types of jet-forming devices, viz. spray nozzles and jet rings, are mentioned and functioning and operation of the latter is described.
