(NASA-TT-F-13338) Avail: NTIS CSCL 20E

Space distribution of condensed matter ejected from metals subjected to laser radiation erosion was investigated to improve spectral analysis sources with simultaneous use of electrical discharge. Laser pulse energy was 7 J and the light was coned by means of a lens. Angular distribution of matter ejected was measured for Cu alloys, Zn, Fe, Fe-Si, Pb, Sn, Al, Mg, and W condensed on a glass plate situated perpendicularly to the laser beam. Maximum density of the condensed material and the angular position of this maximum were plotted as a function of the melting point of the material. Chemical composition of the sample corresponds to that of the ejected material. An arrangement of electrodes for spectral analysis carried out during simultaneous laser function and discharge was proposed.
